On Gibson's (1969) account, perceptual learning entails an increased ability to extract relevant information from a stimulus array as the result of experience. The traditional view of perceptual learning, dating back to Bishop Berkeley in the 1700s, is that animals must learn to perceive; the information at sensory receptors is impoverished and meaningless and thus a complete percept requires learning. In Gibson's view, the information at receptors is sufficient to support complete percepts from the start, and thus animals need not *learn to perceive*; rather, they *perceive to learn* (Gibson, July 1989). Perceptual learning is the key to knowledge and where it all begins.

Gibson (1992) maintained that a theory of perceptual learning must answer basic questions: What is learned and what is the function? What instigates learning and what terminates the process? As for the question of mechanism, Gibson held that meaningful explanations of psychological processes must be at the level of behavior. She always maintained that the job of a perception psychologist is to describe and explain perception at the level of individual behavior, not in terms of the underlying neurophysiology (Gibson and Pick, 2000). Perceptual processes should be consistent with what we know about neural mechanisms and physiology, but these facts should not drive research into perceptual processes. Rather, the appropriate research program should begin with a consideration of what there is to be perceived in an ecological context – what animals need to perceive so as to act adaptively in the natural environments in which they evolved and in the changing environments in which they develop.

Starting Assumptions

Gibson's theory grows out of her commitment to several related starting assumptions that guided her thoughts about perceptual learning and shaped the trajectory of her research career. She believed that J.J. Gibson's (1966, 1979) *ecological approach* to perception is the proper starting place for a theory of perceptual learning and development (Gibson and Pick, 2000). Animals must be considered doing the things that they naturally do in their particular ecological niche. Their activities are guided by perceptual information and such information is available in the ambient arrays of energy to which their perceptual systems are sensitive. Because perception involves the whole animal, nested in its environment, her approach was necessarily a *systems approach*. The total system includes animals in the environment that surrounds them in the here and now and which has shaped them in the course of evolution and development, and which they in turn influence (Gibson, 1992).

Because of her focus on animals in their species-typical environments, hers was a *comparative approach*. In contrast to the traditional practice of focusing nearly exclusively on humans and the chambered eye, she maintained that perception psychologists should consider the perceptual systems and actions of varied species as they build theories of perceptual learning and development in humans (Gibson and Walk, 1960; Walk and Gibson, 1961). All animals have solved the problem of using perceptual information to guide activity: houseflies with compound eyes, fish using

electrolocation, bats using echolocation, and so on. Studying such diversity of form and function will lead to general principles of perception and its development. Evolutionary and developmental pressures are integral to a comparative approach, and perceptual learning – like all behavior – can only be understood in the context of development (Gibson, 1984b). Thus, her theory also begins with a *developmental approach*.

Above all, hers was a *functional approach* to perception and perceptual development (Gibson, 1982). A functional view considers the purposes of perception in everyday activity and over the evolutionary history of the species. Perception does not exist to discriminate Gabor patches or to support other reified laboratory phenomena. The ultimate question for perception researchers should be "how [animals] perceive what is going on around them so as to make good use of what the world offers" (Gibson, 1997: p. 42).

Perceptual Information

The ecological approach differs from traditional theories of perception in the conceptualization of perceptual information (Gibson and Pick, 2000). In the Gibsons' view, the ambient arrays of energy surrounding the observer – light, sound waves, patterns of pressure on tactile receptors, and so on – are structured by the objects and surfaces in the environment in ways that specify those objects and surfaces; thus, information arrives at sensory receptors already richly imbued with structure. This structure is not carried in a static image; it is only apparent in relations that emerge over transformations in space and time (movement of objects or the observer, edges, gradients, flow, etc.). Structured arrays of energy contain the information through which perception of the self and environment occurs (Gibson, 1970). If one only considers rays of light or sound vibrations, specification is not possible.

The task for the perceiver is not to add structure to impoverished sensory stimulation, but to detect the structure that already exists. We do not perceive ambient energy arrays and we do not perceive information. Rather, by detecting information in ambient arrays, we perceive the things in the world that structured the information and that are specified by the information (Gibson and Spelke, 1983).

Starting with this view of perceptual information, it might seem as if the *ecological approach* is at odds with a theory of learning. If information is already structured to specify things in the world, what is there to learn? But Gibson did not see a tension between the two. The organism must learn through experience how to generate and detect the appropriate perceptual information.

Animal–Environment Reciprocity

Animals and their surrounding environment constitute an interactive system, with each constituent reciprocal to the other (Gibson, 1997). Animals generate information about the environment and must tailor their actions to the environment. Reciprocally, the environment provides the animal with "opportunities and resources for action" (Gibson and Pick, 2000: p. 14) and with information that specifies those opportunities and resources. An animal fits into its ecological and developmental niche. The animal is scaled to the environment, as the environment is scaled to it. Muscle fibers and neurons exist, as do light waves and sound waves. But descriptions in such terms do not provide a meaningful link between animals and their environments (Gibson, 1984b). Physicists describe the environment in terms of molecules and galaxies, events in terms of nanoseconds and light years. But the psychologist's description should be on the scale of the animal concerned and the niche it occupies. The appropriate description is an ecological one: The animal's body, capabilities, and propensities must be described relative to the environment; reciprocally, the properties and features of the environment must be described relative to the animal. For example, "a cliff is a drop-off that is large relative to the size of the animal, and a step is a drop-off that is small relative to its size. A falling-off edge is dangerous, but a stepping-down edge is not" (Gibson, 1979: p. 157). Perception takes animal–environment reciprocity into account because to perceive the world is to coperceive the self (Gibson, 1991).

Perception–Action Reciprocity

A corollary of animal–environment reciprocity is perception–action reciprocity. Traditionally, researchers study perception by projecting displays onto observers' eyes or into their ears. But on Gibson's (1988a) account, we do not just see, we look. We do not just hear, we listen. Perceiving is an active process. The visual system, for example, is a motor system as well as a sensory one. It involves more than the retina or even the moving eye. Looking involves the eyes in the head on a mobile body. Perceivers seek information and optimize it rather than passively receiving it. The animal must do something to obtain information – scan the scene, turn the head, palpate the surface, kick the tires. Learning what to do – how to gather perceptual information – is a major part of perceptual learning. Because perceiving goes on over time, it can correct itself in real time and improve over development.

What is all this perceptual activity for? Perception functions to gather information about objects, events, and places and what the perceiver can do about these things (Gibson, 1988b). Perception guides action in a changeable environment. Thus, perception and action operate as a continuous cycle, whereby "perception obtains information for action, and action has consequences that inform perception about both the organism itself and the events that it perpetrates" (Gibson, 1997: p. 25). All actions – walking, cooking, typing, driving a car – must be guided by perceptual information. Reciprocally, action turns up perceptual information about the environment, what the animal is doing, and what it might do next. Gibson (1997: p. 25) differentiated between exploratory action ("foraging for information") and performatory action ("controlling environmental consequences"). But both types of action generate perceptual information, and both are guided by perceptual information.

Learning in Development

Gibson (1994) wrote, "There is just one way to understand behavior, and that is to take a developmental approach. There

is no typical or standard moment of maturity; besides, we gain our understanding from change and becoming" (p. 71). Development, for Gibson (1970), included changes over evolution and in the individual's lifetime. Although fashionable long before she arrived on the scene, and still considered central to current work, Gibson (1994) eschewed the nature–nurture dichotomy. She referred to it as a "hob-goblin that has haunted us" in developmental science (p. 71).

Development involves changes in animals' bodies, perceptual sensitivity, action capabilities, and environments. The developmental course of these changes creates changes in the perception–action loop, and thereby constrains or facilitates perceptual learning and development (Gibson and Pick, 2000). In particular, new action capabilities bring about new ways of generating information and also alter the relevance of the information generated (Gibson, 1988a, 1991, 1992). Recent work on relations between action development and perceptual learning back this up. Objects, for example, take on special relevance once infants acquire manipulatory skills. Accordingly, infants exhibit sensitivity to the three-dimensional form of objects after they can produce coordinated visual–manual exploration, which in turn, depends on the ability to sit independently (Soska et al., 2010).

What Is Learned

Gibson (1970, 1984b, 1992) assumed that a theory of perceptual learning must start with a functional analysis of what is out there to be perceived and learned – the general tasks of perceptual systems across development and species. Only then can researchers tackle subsequent questions regarding processes of perceptual learning. Gibson's focus regarding the content of perceptual learning changed over the course of her career. Her earlier work, influenced by her studies of reading, focused on learning distinctive features through higher order invariant relations (Gibson, 1969). She later asserted that she had been "premature" in concluding that "the principal thing learned in perceptual learning was distinctive features of objects" (Gibson, 1991: p. 394); "the old mistake was to start with static displays in formulating a theory of perceptual learning" (p. 615). Her later work, influenced by her studies of infant action, emphasized learning to perceive affordances and events (Gibson and Pick, 2000). This learning is more dynamic and fundamental.

Affordances

Above all, what animals learn to perceive are affordances for action (Gibson, 1980, 1982, 1992, 2000). *Affordances* are possibilities for action, what the environment offers the animal (Gibson, 1979). Possibilities for action depend on the fit between the animal's bodily capabilities and the physical properties of the environment. For example, a vertical wall affords walking for a housefly but not for a human; a 200-lb dumbbell affords lifting for a bodybuilder but not for a kindergartener. The animal–environment relations exist objectively in the interface between self and world. Affordances thus are real, regardless of whether they are perceived or used. Affordances reflect both animal–environment reciprocity and perception–action reciprocity because affordances must be perceived, perception must guide action, and actions are implicit in affordances. In Gibson's (1982) view, "we do not perceive stimuli or retinal images or sensations or even just things; what we perceive are things that we can eat, or write with, or sit down on, or talk to" (p. 60). We do not only perceive the size or distance of objects. We perceive whether something is within arms' reach and whether it will fit into our grasp. What we perceive are the functional relations between self and world (Gibson, 1980).

Perceptual development is a process of learning about affordances, becoming better able to detect appropriate supports and resources, and discovering new affordances as action capabilities change (Gibson, 1992). Affordances themselves develop. The acquisition of new motor skills – looking, reaching, walking, weight lifting, swimming, driving, sewing, hand writing – produces new affordances to be learned throughout life.

Perceiving affordances is essential for survival; it is what perceptual systems evolved to do. Certainly the best-known empirical example of animals perceiving affordances is Gibson and Walk's (1960) classic work using a 'visual cliff.' The visual cliff studies were Gibson's first foray into work with human infants and the first experiment to show the close tie between perception and action in the human infant. This was an experiment on perceived affordances for action, although she did not conceive it as such at the time (Gibson, 1991). All animals tested, including rats, cats, chickens, turtles, monkeys, and human infants, readily cross a visible surface that affords locomotion (the 'shallow side') and refuse to cross an apparent drop-off that does not (the 'deep side'). Later work inspired by these classic studies revealed that, for some species including cats and humans, a period of self-produced locomotor experience is necessary to learn to perceive affordances and thereby produce avoidance of a drop-off (Adolph, 2000; Bertenthal et al., 1984; Held and Hein, 1963; Kretch and Adolph, 2013).

Events, Invariants, and Multimodal Information

According to Gibson (1969), perception is a process of information pickup that happens over time. *Events* therefore are the primary source of perceptual information and a critical component of what is learned during perceptual learning and development. "Happenings over time" (Gibson, 1969: p. 16) include events perpetrated by the perceiver (throwing a ball), events that will soon involve the perceiver (an approaching ball to be caught or dodged), and events that are merely observed and external to the perceiver (watching others throw and catch). Infants are sensitive to all these types of events (Gibson and Pick, 2000).

Many critical sources of information only emerge in the context of an event (Gibson, 1979). Optic flow and motion parallax, for example, emerge as an animal moves through the world. Accretion and deletion of visual texture elements occur when an object or part of the layout becomes progressively uncovered or occluded. Time-to-contact information – the rate of change in visual flow, air pressure, sound, and so on – emerges as an object approaches the observer or another target (Lee, 2009). In the course of an event, some things change and some things do not. The relations that remain

invariant under transformation can specify what is permanent and what is changing and how the change is occurring (Gibson, 1979). As an object moves through different locations, it causes particular patterns of transformation in the optic array. Through these patterns of transformation, we perceive it as the same, unitary object and we simultaneously perceive its trajectory and manner of motion through the layout. Invariant information for unity and constancy is abstract and relational; it must be invariant over change, and it has a higher order structure (Gibson, 1984a). A looming object on an approach trajectory is an obstacle if the expansion pattern causes increasing, symmetrical deletion of background texture. The object is an aperture – a window to look through – if it progressively reveals more background texture in the middle of the display. By 3 months of age, infants blink and retract their heads at the approach of a looming obstacle on a collision path to their face, but lean forward to peer through an approaching aperture (Gibson, 1982; Gibson and Schmuckler, 1989; Schmuckler et al., 2007). Crabs, frogs, kittens, and other animals do likewise (Gibson, 1970).

Information can be detected in different modalities – through looking, feeling, hearing, and so on. In the natural environment, information for affordances and events is typically multimodal (Gibson, 1984a, 1992). Direction of self-locomotion, for example, is specified redundantly by patterns of visual flow, vestibular information, proprioceptive information from muscles and joints, and occasionally auditory input. A communication event between infant and mother is specified redundantly by mother's facial movements, the synchronous sounds emanating from her mouth, and the contingent, causal relations as the infant responds in turn. Infants do not need to learn to paste percepts from different modalities together. Rather, information from different modalities belongs together when it is unified by the same invariant relations, typically occurring in the same event. Infants demonstrate multimodal perception of rigid and deformable motions, for example, through viewing and feeling hard and spongy objects, either held in their hands or in their mouths (Gibson and Walker, 1984). They do likewise for rigid and deformable ground surfaces by viewing an event on the surface and by creating events through actively palpating the surface (Gibson et al., 1987; Joh and Adolph, 2006). In cases involving temporal synchrony, rhythm, and intensity, the invariants are amodal, meaning the information is not specific to a particular modality; it is the same in every modality (Gibson, 1984a, 1984b).

Distinctive Features

Based on her research on learning to read, in her earlier formulations of what is learned, Gibson (1969, 1977) emphasized learning to detect the *distinctive features* of things in the world. Distinctive features are the relational contrasts or minimal set of attributes that distinguish one kind of thing from another. For example, the distinctive features of written letters include the presence or absence of straight lines, curves, and symmetry. When learning to read, children must learn to detect these distinctive features that, in different combinations, specify particular letters (Gibson and Levin, 1975). Distinctive features are relational properties that are invariant under certain transformations; growing a letter in size or distorting its slant does not change the critical information, whereas reversing the letter or changing the topography does. Importantly, not every characteristic of a stimulus is a distinctive feature. In the case of letters, color and line thickness are not distinctive features that distinguish one letter from another. Discrimination occurs when, "out of a mass of stimulus properties emanating from a set of objects, the perceiving organism learns to choose only those necessary for distinguishing between the objects" (Gibson, 1969: p. 140).

Although Gibson's early work on distinctive features was inspired by her research on reading, the processes are presumably more general. Reading relies on perceptual processes that evolved for other purposes and are shared by other animals. Controlled rearing studies in animals provide evidence of learning to discriminate among sets of objects by discovering the particular features that distinguish them (Gibson and Walk, 1956). Nonetheless, Gibson (July 1989) asked, "Do infants progressively learn to select out distinctive features of the things around them, as I once thought? Maybe. But that is not where perceptual learning begins. I think it begins with learning affordances: what properties of the environment have utility for what actions" (p. 14).

Process of Perceptual Learning

Perceptual learning is an increased ability to detect information specifying affordances, events, and distinctive features. In Gibson's (1992) view, "perceptual learning is first and foremost a process of selection" (p. 217); perceptual information becomes increasingly differentiated and specific to the self, the world, and the relations between them. Exploratory activity is the primary behavioral mechanism for generating perceptual information and for differentiating information from the flux. Through spontaneous exploratory activity, animals seek information for guiding actions adaptively. This search for information is as integral to animals' nature as breathing (Gibson, 1970, 1977). What is extracted at any moment depends on the animal's evolutionary history, its level of development and learning, and the activities it is engaging in – what it is currently doing and what it wants to do next (Gibson, 1994). During a bout of exploration, the search for information terminates with a significant reduction of uncertainty (Gibson, 1969). However, animals are always searching for increasing specificity of information for affordances; over learning and development, there is a continual increase in predictability and efficiency of perceiving what is doable (Gibson, 1991, 1992).

Differentiation and Increasing Specificity

According to Gibson (1977), infants perceive objects, events, and the layout of the environment from the start. Perceptual learning is the process whereby perceptual information becomes increasingly differentiated and specific to the things in the world and to what one can do with those things (Gibson, 1992).

Gibson's focus on *differentiation* and *increasing specificity* sets her theory apart from traditional theories of perceptual

learning. On the traditional account, perception requires more than the available sensory stimulation; thus, perceptual learning is a process of learning to construct, supplement, infer, hypothesize, interpret, organize, associate, or otherwise enrich impoverished input. Gibson and Gibson (1955) pointed out that the traditional enrichment view requires perceptual learning to produce percepts that *decrease* in correspondence with the available information. The Gibsons proposed to the contrary that perceptual learning should result in percepts that *increase* in correspondence with the available information. Rather than an add-on process, on their account, perceptual learning is a process of differentiation, selection, and extraction of information; the information was always present, just not previously detected. They theorized that learning is a process of "differentiating previously vague impressions," not "enriching previously meager sensations" (Gibson and Gibson, 1955: p. 34). Perception does not improve through constructing new descriptions of the world, but through discovering new information about it (Gibson, 1978; Gibson and Spelke, 1983).

A good, intuitive example of increased specificity through differentiation is wine tasting; a novice wine taster can only distinguish reds from whites, whereas a connoisseur perceives differences that correspond to specific grapes, regions, and sometimes even harvest years. Over years of practice, small differences – differences that truly exist in the chemical signatures of different wines – become more easily distinguished; an expert taster can identify a Bordeaux from France and distinguish it from a similar mix of Cabernet Sauvignon, Merlot, and Cabernet Franc grapes from California. Other everyday examples abound: Experienced drivers can easily perceive whether the spot is sufficient for parallel parking or the gap in moving traffic will allow merging or switching lanes; experienced listeners can distinguish the cellos from the violins and the clarinets from the oboes; expert radiologists can distinguish a cancerous spot from normal breast tissue on a mammogram or a fracture from a normal vascular groove on an X-ray. In the laboratory, perceptual learning follows the same course, proceeding from murky undifferentiated percepts to increasing specificity. For example, with practice, adults can learn to use gradients of texture density on a large lawn of mown grass to estimate the distance between targets (Gibson and Bergman, 1954; Gibson et al., 1955; Purdy and Gibson, 1955). Infants learn to distinguish between two types of structure in optic flow, radial versus lamellar flow, using the former for steering and the latter to control upright balance (Stoffregen et al., 1987). In each case, the invariant information was there all along to be differentiated. Targets of perception that were once confusable and undifferentiated become increasingly discriminable with practice (Gibson, 1963).

Not all the available information is relevant for the task at hand. We never detect the total stimulation reaching our receptors. Instead, we sample from this vast pool so that only part of the potential information becomes effective. The key to perceptual learning is the *education of attention* – learning which variables to attend to and which to ignore. Through practice and experience, attention becomes fine-tuned toward the relevant information (Gibson and Spelke, 1983). Attention relates perception to action and to a person's needs and motives (Gibson and Rader, 1979). Search is part of attending. The more perceivers know what is wanted and where and how to look for it, the less they bother with irrelevant and unhelpful information in performing a task. Perceptual learning seeks the minimal information that differentiates one thing from another. Reducing the information to just what is needed is typical of skilled performance. Detecting order, invariance, and redundancy are ways of achieving specificity and economy.

Exploratory Activity

For Gibson (1994), exploratory activity is integral to the process of perceptual learning. Animals forage for information about the relations between self and the surrounding environment (Gibson, 1997). Evolution provides animals with perception–action systems that equip them to discover what the world is all about; the development of these systems provides the motivation to explore the accessible surround, act on it, and further extend explorations as capacities grow. Vision is an especially powerful motivator because it provides information about the world at large (Gibson, 1978). Human infants begin by looking around. Anything in a baby's field of view can provide an incentive for exploration. Before they acquire independent mobility, infants reach for the things that they see. After they can locomote, babies crawl toward and finally walk and run for the attractive goal at a distance.

Exploratory activity includes behaviors such as scanning, fixating, feeling, mouthing, licking, listening, whisking, sniffing, and manipulating – seeking information using whatever actions and body parts are most currently suited for efficient search (Gibson, 1970). Multimodal exploration is the norm. Although all movements produce perceptual information, Gibson (1988a) believed that deliberate, focused exploratory behavior has special importance for perceptual learning: "A sequence of acts termed exploratory will have some outcome and will not be random. It will have a perceptual aspect, a motor aspect, and a knowledge-gathering aspect" (p. 5). Observing the consequences of exploratory actions leads to learning.

Exploration develops and the development of exploratory activity facilitates and constrains perceptual learning (Gibson, 1988a). Long before birth, animals have movements in their repertoires and are sensitive to ambient stimulation. So these movements and sensitivities can be harnessed immediately. As new perception–action systems become available, they are tried out for use in the service of searching (Gibson, 1997). In human infants, the development of postural control (head, trunk, and finally the whole body) opens up new opportunities for exploration and perceptual learning (Gibson, 1988a). In the first few weeks of life, infants gain control over their eyes and head. This enables active scanning of the visual world. In this period of development, infants learn about objects, people, and events by actively directing their gaze toward points of interest. Several months later, infants acquire independent sitting. This frees up their hands and leads to improvements in manual skills. They gain the ability to explore objects with their hands, to coordinate visual inspection with manual actions, and to pass objects back and forth from mouth to eyes. In this period

of development, they learn about the physical properties and affordances of objects. Toward the end of the first year, when infants begin to crawl and to walk, the wider world becomes available to them. In this period, they use locomotor exploration to learn about the properties and affordances of surfaces, places, and the spatial layout. In this way, perceptual-motor development is the driver of early perceptual learning. Emergence of a new action system, such as walking, instigates exploratory activity that generates information about the body's new and changing capacities and about properties of the environment that are implicated in the new activity (Gibson, 1988b). Practice with particular exploratory activities may result in optimizing the search or elaborating it with more complex forms of coordination like using the hands for different roles in manipulation. At any point in development, exploratory activity can be extended with tools such as a rattle or hammer in hand, or a handrail lining a staircase, or by putting instrumental means at infants' disposal by yoking their leg kicks to an overhead mobile, or connecting a pressure-sensitive pacifier to a recording or slide show (Gibson, 1992).

Hallmarks of Human Behavior

Toward the end of her career, Gibson (1994, 1997) expanded her theory of perceptual learning to encompass the hallmarks of human behavior – the fundamental aspects of human behavior that psychologists need to understand and explain. These hallmarks are inherent in behavior and are specific to behavior; they do not exist in lower level physiological descriptions. Each hallmark develops, and Gibson believed that describing their development is at the heart of developmental psychology. Three major hallmarks are agency (the self in control), prospectivity (the forward looking direction of activity), and behavioral flexibility (transfer of means and strategies to new situations). All three require and promote perceptual learning.

Agency

One of infants' great discoveries is that it is possible to effect change on the world by controlling an observable event through one's own action. This realization comes about through motor activity and perceptual learning. It is the hallmark of *agency* and it is discovered very early in development (Gibson, 1995). Gibson and Pick (2000) wrote, "infants learn at a remarkably early age that their actions have an effect on the environment, that some events going on around them are amenable to their control, and that they can in fact regulate their own actions" (p. 160).

One of Gibson's favorite examples of achieving control is that infants increase their rate of kicking when their foot is tied to an overhead mobile, such that the jiggling mobile elements are contingent on their kicks (Rovee-Collier and Geloski, 1979). Another favorite finding is that infants increase their rate of sucking on a nonnutritive pacifier when the sucks are linked to the sound of mother's voice or bring a slide show into focus (DeCasper and Fifer, 1980; Kalnins and Bruner, 1973). Infants in control groups do not kick or suck differently from baseline when the contingencies do not exist. Although the mobile and nonnutritive sucking paradigms are examples of instrumental conditioning, in Gibson's (1992) view, these are not simply examples of associative pairing. The reinforcer is not the jiggling mobile elements or the voice. It is control over the environment that is rewarding. Indeed, infants' emotional expressions are linked with the sense of control. They display happy expressions when the contingency is working and angry expressions when the contingency is broken during extinction (Lewis et al., 1990, 1985). Yoked controls who see the same displays exhibit only interest and neutral facial expressions. Infants detect the relation between their own exertion and the environmental change just as they perceive the sequence of cause and effect.

What is learned in the development of agency? Infants acquire a sense of a self that is separate from the world, and that can act intentionally on its own powers on the world (Gibson, 1997). Perceiving oneself as a source of control that causes perceptible changes in the world is the epitome of perceiving oneself (Gibson, 1995). In answer to William James' (1879) famous question, "Are we automata?" Gibson's (1995) answer was no.

Prospectivity

Behavior extends over time. At any moment, perceptual consequences of the preceding actions inform the planning of subsequent actions (Gibson and Pick, 2000). *Prospectivity* refers to the forward-looking quality of behavior. To select and perform actions adaptively, perception must be planful and prospective. Many of the ideas that were most important to Gibson were linked to prospectivity. For example, perception of affordances implies perceiving possibilities for potential future actions, and guides planning of future actions. Exploratory behavior is used prospectively to generate information for planning actions. Agency and control also imply prospectivity because agents have an eye toward the future consequences of their actions.

Infants show evidence of prospectivity very early in development, although planning improves with learning and experience. For example, before infants raise an arm to reach, their abdominal muscles activate to stabilize their posture, anticipating the disruption to balance caused by raising the arm (von Hofsten, 1993). Infants bring their hand to the location where a moving object will arrive so as to intercept it (von Hofsten, 1980) and they begin to close their hand in anticipation of grasping the object rather than as a reaction to encountering the object (von Hofsten and Ronnqvist, 1988). As infants learn more about what leads to what, and pick up information about the causal relations in events, the prospectivity of behavior increases.

Flexibility

One of the most impressive hallmarks of human behavior is its flexibility. *Flexibility* refers to the generation of new means and strategies and their transfer to novel and variable environmental and bodily conditions and to the task at hand (Gibson, 1994). Affordances constantly change, so "stereotypy of reaction is perilous" (Gibson and Pick, 2000: p. 169).

For example, goats produce a variety of reactions when they receive an electric shock signaled by a buzz or light – walking/running backward or forward, walking in circles, side-stepping, independent leg movements, foreleg flexion, foreleg extension, humping the back, rearing, and so on – until they discover the

behavior that works to avoid the shock (Gibson, 1952). Humans also show a variety of strategies, and they can transfer means that work in one context to another. In her first published paper (Gibson et al., 1932), Gibson found that adults who were conditioned to withdraw the index finger of one hand to avoid a shock transferred the means of avoidance to the index finger on the other hand when told to place that finger on the electrode.

Infants also generate a variety of means and strategies. When tested at the brink of shallow and steep slopes, infants correctly perceived affordances for walking (Adolph et al., 1993). Moreover, on the steepest slopes where walking was impossible, infants generated new means of descent: sliding down backward feet first, in a sitting position, and belly-down headfirst. Are these alternative means of descent transferable? Yes, when discovered over weeks of crawling, infants can use the same sliding strategies to descend slopes after they begin walking (Adolph, 1997).

Flexibility improves with learning and development. Expansion of the repertoire of available actions provides more options for confronting novel challenges. Moreover, experiencing new environmental conditions provides opportunities to generalize old skills to new settings and to develop new solutions on the fly (Gibson, 1997).

Conclusions Beyond Perception

Gibson's theory of learning extends beyond perception and the hallmarks of human behavior. Many psychologists think of cognition exclusively in terms of problem solving, reasoning, conceptualizing, remembering, and so on. However, Gibson (1991) points out that these processes, like the hallmarks of behavior, "begin with and depend on knowledge that is obtained through perception" (p. 494). Cognition is built on a foundation of perceptual knowledge. "Perhaps knowledge eventually becomes a system of representations and beliefs about the world … but … representations and beliefs must be grounded by detection of the surfaces, events, and objects of the layout—the 'stuff' of knowledge must somehow be obtained from the world" (Gibson, 1988a: p. 34).

Acknowledgments

The writing of this article was supported by National Institute of Health and Human Development Grant R37-HD33486 to Karen Adolph and a predoctoral National Science Foundation fellowship DGE-0813964 to Kari Kretch. We are grateful to Mark Blumberg, Anne Pick, and Harry Heft for their helpful comments and to Eleanor "Jackie" Gibson for sharing her unpublished manuscripts and talks.

Abstract

Anthony Giddens is perhaps Britain's leading sociologist, renowned especially for his theories of structuration and late modernity, and his championing of 'third-way' politics. This article outlines Giddens work in terms of four overlapping phases focusing on his early writings, his theory of structuration, his theory of modernity, and finally his writings in politics and social policy. It concludes by arguing that although Giddens provides some insights in his sociology, his work is underpinned by a number of theoretical and substantive failings which ultimately derive from his liberal worldview and include an overemphasis on agency and a downplaying of conflict, and social and material interests as fundamental characteristics of the social world.

Anthony Giddens is perhaps Britain's leading sociologist, renowned especially for his theories of structuration and late modernity, and his championing of 'third-way' politics. Born in London in 1938, he attended the University of Hull and graduated in 1959 in Sociology and Psychology. He studied for a master's degree in Sociology at the London School of Economics, and in 1961 became a lecturer in the Department of Sociology at Leicester University. He held positions at Simon Fraser University and the University of California at Los Angeles before moving to King's College Cambridge. He formed Polity Press in 1985 and became director of the LSE in 1997. His growing status as the most visible intellectual proponent of 'third-way' politics drew him into the inner circle of British Prime Minister, Tony Blair, and in 2004 he was given a life peerage as Lord Giddens of Southgate.

Giddens's intellectual career is best understood in terms of four overlapping periods, each marked by a distinctive set of theoretical concerns. His early work, 1970–75, focused on the exposition of the classical tradition of European sociology, and Giddens was influential in establishing the canonical trilogy of Marx, Weber, and Durkheim as the basis of social theory. Subsequently, until 1989, he focused on the possibility of transcending a series of perceived dualisms within social theory, most significantly that between agency and structure. The resulting theory of structuration led to an attempted rewriting and reperiodizing of human history. The third phase of his career, 1990–93, developed these theoretical and temporal insights into a more substantive analysis of the contours of modernity and the contemporary stage of what he referred to as 'late modernity.' This prepared the way for the most recent phase in his work, in which he moved from sociology to more directly political–theoretical concerns. Giddens presentation of the 'third way' can be seen as an application of his earlier theoretical work on 'dualisms': an attempt to transcend the dichotomy between left- and right-wing political ideologies.

His first major book, *Capitalism and Modern Social Theory* (1971), not only set out a comprehensive exposition of the sociological ideas of Marx, Weber, and Durkheim, but also reexamined significant areas of convergence and divergence. Rather than converging around an implicit, if abstract, Hobbesian 'problem of order,' these three were instead concerned with the substantive historical–sociological problem of the profound rupture separating capitalism from prior feudal or traditional social formations. Their politics sought to synthesize liberalism and revolutionary or radical forms of thought in different ways. Giddens developed some of these ideas in, *The Class Structure of Advanced Societies* (1973), synthesizing Weberian and Marxist views of class.

His most significant contribution to social theory, the theory of structuration, was an attempt to overcome the division between sociological approaches that emphasize agency and those that emphasize structural constraints. The former focus on self-conscious agents – their intentionality, subjectivity, knowledgeability, and ability to construct, create, or make the social world they find themselves in. Advocates have included phenomenology, ethnomethodology, symbolic interactionism, and rational choice theory. Structural theories, on the other hand, place more emphasis on objective factors, the social determination of the self, and the invisible forces and emergent dynamics that shape the actions, perceptions, and 'second nature' of individuals. These have included functionalism, structuralism, and the many varieties of Marxism. The agency/structure dualism that informs these two traditions runs through a series of related perspectival and methodological tensions that plague the discipline: individual *versus* society, micro *versus* macro, and subjective *versus* objective.

In his theory of structuration, Giddens argues that the agency/structure dualism can be overcome only by synthesizing insights from a variety of otherwise flawed perspectives. This involves a reformulation of the lexicon of sociological concepts. For Giddens, prior theoretical applications of the term 'structure' – most significantly those found in functionalism and Marxism – tended to define structure as causally efficacious patterned social relationships that are not only external to human agency but also constraining upon it. He discerns a very different understanding of 'structure' in Levi-Strauss's structuralism. Structure here refers to abstract models in the form of binary oppositions and dual relations, existing in and through human beings and that do not exist in time and space but as relations of presence and absence. Utilizing this latter approach, Giddens offers his own novel definition of structure. Structures, like languages, are 'virtual' since they exist 'outside of time and space,' are 'subjectless,' and are, for the most part, unintentionally reproduced in practices. By identifying structure with language, he hoped to effect a dynamic

juxtaposition between the speech or action implemented by an agent and the structure that forms the condition of possibility for generating this speech and action. This had two effects. First, there is what Giddens refers to as a 'duality of structure': structure is no longer understood as simply constraining but also as enabling. Structure not only limits action through rules of 'syntax,' it also makes possible the generation of action. Secondly, structure is both the medium and the outcome of action. Hence, the 'instantiation' of structure in individual action recursively draws upon and reproduces structure in a manner akin to a speech–act drawing upon and reproducing the totality of language. Every act of social production is therefore simultaneously an act of reproduction.

For Giddens, structure and agency form two sides of the same coin and are connected through social practices. They are inseparable dimensions of the flow of activities in which individuals participate during the course of their day-to-day lives. Specifically, he sees structures composed of rules and resources. Rules may be explicit or tacit, intensive or shallow, formal or informal, strongly or weakly sanctioned, but should generally be understood, in Wittgenstein's sense, as practical forms of knowledge that 'allow us to go on' in novel circumstances. Resources are 'authoritative' capabilities that generate command over persons or 'allocative' capabilities that generate command over objects or other material phenomena.

In addition to rethinking the concept of structure, Giddens also reconceptualizes the concept of agency. In his stratification model of action, he draws upon and modifies the Freudian schema of agency to argue that an actor's consciousness has three aspects: discursive consciousness, practical consciousness, and unconsciousness. Loosely corresponding to this threefold division of the consciousness, he refers to reflexive monitoring, rationalization, and the deep motivations for action. Practical consciousness and its rationalization as the tacit or 'mutual' knowledge that provides agents with the ability to 'go on' in relation to rule-bound social life is most significant for understanding social life.

Although free to choose, agents follow routines to avoid ontological insecurity and any disruption of the basic security system internalized during childhood. Drawing on Merton's classic essay on the unintended effects of purposive action, however, Giddens argues that an individual's intentional acts often produce unintended consequences. These unintended consequences then become the future unacknowledged conditions that structure the subsequent action of the agent.

A second aspect of Giddens's structuration theory relates agency to power, arguing that an agent ceases to be such if s/he loses the ability to 'act otherwise.' However, given that there exists a 'dialectic of control' built into the very nature of agency and involving the interplay of autonomy and dependence, a total loss of agency is rare.

In parallel with the development of the theory of structuration, Giddens produced his own historical sociology as a 'positive critique' of Marx's historical materialism, which he considered as economically reductionist and methodologically suspect. In *A Contemporary Critique of Historical Materialism* (1981), he repeats a number of criticisms he has made against Marxism. These include the recognition that (1) there is a need for a distinction between capitalism and industrialism; (2) political factors have played a far more significant role in the latter-day development of advanced societies than Marx had envisaged; (3) the preeminence of 'traditional' elements in the capitalist societies is tied to the rise of nationalism; (4) the study of the nation state within its international context is crucial; (5) there is a need for a move away from evolutionary and endogenous models of social change; and (6) Marxism fails to recognize the influence of military factors in social change. He then elaborates a nonfunctionalist, nonevolutionary, nonteleological, multidimensional, and historically contingent view of social change. His historical schema incorporates a tripartite societal typology that distinguishes tribal class-divided societies from class societies. These societies are defined according to their level of social and system integration and time–space distanciation. Social integration, refers to 'systemness' in circumstances of 'copresence' or 'face-to-face' interaction, not only emphasizes the spatial significance of presence but also attempts to convey the importance of the 'positioning' of the body within social space. By contrast, system integration refers to the reciprocity which exists between actors or collectivities across extended time–space or in relation to absent others outside of the conditions of copresence. This involves a process of 'time–space distanciation': the 'stretching' of social systems across time and space. In *Nation-State and Violence* (1985), he develops and modified this framework, exploring the complex symbiotic codevelopment of capitalism, industrialism, and the nation-state. For Giddens these three spheres provide the basis for the four irreducible, though connected, 'institutional clusterings' that characterize modern society: capitalistic enterprise, industrial production, heightened surveillance, and centralized control of the means of violence. This characterization of modernity is developed further in the third phase of his work. In *The Consequences of Modernity* (1990), Giddens argues that the critical feature of the dynamic social formation that began to develop in Europe from about the seventeenth century was its sharp, qualitative discontinuity from the previous, traditional social order. This break involved a profound transformation, that is, both global and personal.

Underlying modernity are three sources of dynamism: distanciation, disembedding, and reflexivity. The 'separation and recombination of time and space' facilitates and promotes an increased 'zoning' of social life. Everyday encounters and interactions become less tied to fixed locales and less dependent on the copresence of the individuals involved. This, in turn, facilitates the development of modern rationalized organizations, and permits the emergence of a radical historicity in which the past can be appropriated with the aim of shaping the future. More importantly, it facilitates the 'disembedding' of social systems. Disembedding refers to the 'lifting out' of social relations from their local contexts of interaction, which permits their restructuring across larger spans of time–space. Modernity is inherently globalizing, so that time–space distanciation links the local with the global through disembedding, although there may also be processes of 'reembedding' in which disembedded social relations are again pinned down. The two major types of disembedding mechanism are 'symbolic tokens' and 'expert systems.' Symbolic tokens are media such as money that can be exchanged, regardless of who uses them, while expert systems are systems of technical accomplishment and professional

expertise such as those of doctors, lawyers, architects, and scientists.

Fundamental to both mechanisms, as well as to the reflexivity of modernity more generally, is the concept of trust. A sense of trust in processes, people, and things is a crucial factor in maintaining a sense of ontological security in the modern world, since its absence results in existential angst or dread. By contrast with premodern societies, where trust and risk were anchored in the local circumstances of place, rooted in nature and characterized by hazards from the physical world or violence in social life, modernity offers a new 'risk profile' characterized by 'manufactured risk.' Here the pervasiveness of socially organized knowledge in the form of abstract systems means that risk becomes the defining parameter of modern culture and life, even replacing the preoccupation with wealth. As Giddens notes "The possibility of nuclear war, ecological calamity, uncontainable population explosion, the collapse of global economic exchange, and other potential global catastrophes provide an unnerving horizon of dangers for everyone" (Giddens, 1990: 125). Giddens's analysis of modernity leads to the conclusion that in place of the two classic sociological accounts of the experience of modernity – Marx's theory of alienation and Weber's 'iron cage' of bureaucracy – the discipline would be better served by his own image of modernity as a careering juggernaut.

Although in his structuration theory, reflexivity is a fundamental feature of social action, it takes on a special meaning in Giddens's theory of modernity. Under emerging conditions of 'wholesale reflexivity' everything (including both individuals and institutions) becomes open to reflection and self-monitoring, including reflexivity itself. Social practices are continually examined and reexamined in the light of incoming information and processes of self-evaluation.

This leads Giddens to consider the transformation of the intimate and personal features of day-to-day existence in modernity especially in his books, *Modernity and Self Identity* (1991) and *The Transformation of Intimacy* (1992). Increasingly, the pressures of work and domestic life push individuals toward the continual reconstruction of self-identities as part of a reflexive project. In this increasingly unavoidable autobiographical project, individual choices are made in the context of an array of trajectories and options engendered by abstract systems. Modernity involves both a transformation of lifestyle and a 'transformation of intimacy' in which personal and erotic ties are formed as 'pure relationships.' According to Giddens, 'pure relationships' involve 'commitment' and demands for intimacy, such that trust develops through mutual disclosure alone, rather than (as in more traditional societies) through criteria – such as kinship ties, social duty, or traditional obligations – that exist outside of the relationship itself.

Building on this theory of modernity, Giddens set out a general political program. In *Beyond Left and Right* (1994) and *The Third Way* (1998), he considered how radical politics might be rethought, both theoretically and in practice, in the context of a changing modern world. What he refers to as 'third-way' politics involves a reevaluation of socialism, social democracy, and conservatism in the light of the altered social conditions of modernity that ultimately renders them inoperable. He argues that the collapse of communism has made the distinction between the political 'Left' and 'Right' superfluous. Consequently, the idea of a fixed left/right binary for Giddens needs to be supplanted by the notion of a radical center or 'active middle' embodying a 'utopian realist' position.

The fostering of an active civil society became a central focus for third-way politics. This involves the state and civil society acting in partnership with one another to provide material and social support for local groups to engage in 'generative politics' orientated toward empowerment. Echoing Beck's discussion of the importance of 'subpolitics' in an era of risk society, Giddens also argues that increasing individualization and reflexivity has led to new forms of democratization or 'dialogic democracy.' In some ways following Habermas's theory of communicative action, this 'democratization of democracy' presupposes uncoerced discussion as a basis for agreement. Rather than referring to the extension of social and civil rights, dialogic democracy points toward a 'deliberative democracy' where forms of social interchange, social solidarity, and cultural cosmopolitanism can be established. Widening democracy also requires a decentralization of the state, or what he calls 'double democratization,' and a move away from the paternalism of the welfare state.

A further consequence of 'reflexive individualization' has been the reevaluation of traditional left-wing understandings of emancipation as pertaining to 'life chances' and freedom. Such emancipatory politics must now be supplemented with a 'life politics' that breaks out of the restrictive cast of class politics. Concerning rich and poor groups alike, this life politics addresses universal issues, less driven by the polarities of social class: that is, issues pertaining to lifestyle, leisure, consumption, and identity. Giddens also argues for a 'new mixed economy' that would correspond to the realities of 'post-scarcity society' and in which a production orientation is replaced by ideals of self-actualization.

These public policy arguments are further developed in *Europe in a Global Age* (2006) in which he argues that European societies must rethink their welfare state model in the light of globalization, and that they must transform them in terms of addressing changing people's changing lifestyles. Two further books develop and extend these arguments. In *Over to You, Mr Brown* (2007), while reviewing the successes and failures of the New Labor Government between 1997 and 2007, he argues that overall the legacy of the party has been positive though new ideas and a new policy outlook are needed in the future. These include a move away from the New Democrats in the United States, which initially shaped the third-way agenda. They also include a more market and business friendly outlook and a commitment for Labor not to put up taxes. Although societies need to be more egalitarian this has to be done in tandem with maintaining economic dynamism and creating jobs. Here he advocates institutionalizing a policy of 'flexicurity' (flexibility plus security) in the labor market. Devolution in terms of power to local and regional authorities needs to be combined with decentralization in healthcare and education. While lifestyle change has to take center stage in Labor's new political concordant with the public and be regulated by the four major forces in society working together: state, business, voluntary or third sector groups, and citizens. Giddens also argues that multiculturalism in which different cultures and communities come together and respect one another through dialogue is to be championed but within a context where immigration is

regulated to prevent the entry of unskilled workers into the country. In *The Politics of Climate Change* (2007), written in the same year, Giddens discusses the political implications and policy parameters pertaining to climate change and energy security, introducing what he rather immodestly calls 'Giddens's Paradox' into the climate debate. This states that since the dangers posed by global warming are not tangible or visible in day-to-day life people will generally remain passive in relation to climate change. However, waiting until they become visible and acute will be too late. The book is a developed analysis of the political innovations required to limit climate change and to this end a plethora of further policy concepts are unraveled. These include an 'ensuring state' – a state that facilitates emissions capping, promotes technological innovations, and supports the innovative role of markets. Other proposals and concepts include the fostering of 'political convergence' – which refers to how far climate change policy overlaps with other values and political goals, as well as 'economic convergence' which concerns how far economic and technological innovations that are developed to combat global warming also generate competitive advantage to those who deploy them. Giddens also talks of a 'development imperative' in which poorer nations, which have only added marginally to global warming, are allowed to develop and are aided by technology transfer from richer nations. At the same time as rejecting green and conservationist arguments based on the precautionary principle of not interfering with nature Giddens posits a positive view of risk, seen as opportunity rather than danger, as the basis for a model of a low-carbon future. This in turn would be based on a politics of convergence in which the left and right on the political spectrum, as well as rich and poor countries, would come together and cooperate on forging long-term climate policies and sharing the fruits of technological advances. Such long-term planning policy though requiring state regulation and intervention would not be dependent upon a top–down state but rather the aforementioned ensuring state.

Giddens's has often provided commendable commentaries on many sociological debates as well as offering unique insights into the nature of the social world. And it is probably here that his strength as a sociologist lies. He has been criticized, however, for his eclecticism, inconsistency, and the lack of empirical utility of his theoretical input. The theory of structuration has been of little use in substantive sociological case studies or field work, and it does not even appear in his own later policy-oriented studies and arguments. More specifically, he has been criticized for placing an excessive emphasis on individual agency, especially in his theory of structuration. It can be argued that Norbert Elias and Pierre Bourdieu provide more fruitful approaches for transcending various sociological dualisms that he was concerned with. It has also been noted that his politics evidences a strong liberal idealism, which underpinned his theory of structuration and historical sociology as a worldview. His more recent political and policy discussions, rather than renewing social democracy as claimed, reflect the influence of a post-Thatcherite neoliberal consensus, often entailing anodyne commentaries on how common goals can be pursued by divergently positioned social actors. These claims are most evident in the sweeping prescriptions of the putative 'Third Way,' which because again based ultimately on a liberal doctrine lead him to ignore the entrenched and unequal distribution of power, and the embedded nature of conflict and social interests – including ethnonational conflicts, struggles over money, private property, and wealth – that exist at both the national and global level in the contemporary world.

Gift: History of the Concept

Abstract

It is impossible to speak about the gift without evoking the figure of the ethnologist and sociologist Marcel Mauss, nephew of Emile Durkheim, who anchored the concept of the gift in the tradition of social sciences with his essay *The gift* (1923/24). Mauss shows that the gift is polysemous. Its meaning changes according to the objects or the events to which it has been attributed, even if Mauss thinks of being able to propose a general scheme of the gift as the triple obligation to give, to take, and to return the given things. This scheme was the object of many debates in social sciences which contributed to highlight the forms of the gift in the various cultures of the world and in their history. This article reconstructs the main arguments put forward about the gift starting with Marcel Mauss contribution on the gift as a total social fact.

The Gift as a Total Social Fact

Marcel Mauss (1872–1950) and his *Gift* build the convergence point of the broad majority of the works carried out on the gift at an international level in several disciplines such as ethnography and ethnology, the sciences of religions, sociology, economy, and the linguistic. In *The Gift*, Mauss succeeds in synthesizing these research results regarding the operations related to the gift, putting them at the same time in an historical and intercultural perspective. The gift is an exchange formed by three obligations: the obligation to give, the one to take, and the one to return the given things. Two words are critical for Mauss. First, the 'given things' are not only presents, but every possible things, as well as human beings, services, everyday and magic/religious rituals, or offerings. Second, the gift always means a 'mutual obligation' shared by all actors in society. It is not a mechanical give-and-take. It involves all actors in societies in broad exchanges taking place in the long run. Finally, the gift retains the ambivalent property suggested by his name, meaning at the same time 'present' and 'poison.' To give the gift, and to take it put the actors in a cycle of obligations to return the gift in a certain manner and in a given time. If these manners are not respected, the actors are likely to lose face, or even to die. Thus, the gift is not a generous sacrifice only, or the expression of gratuity. It challenges the actors who should show that they can give, take, and return gifts in an appropriate way.

Mauss works out his conception of the gift considering the sumptuary forms of consumption in the Kwakiutl and Eskimo societies described by Franz Boas. Mauss pays attention to one of the most spectacular of them, the *potlatch*, the ceremonial destruction of the most invaluable goods of a tribe at regular intervals of time in order to balance property in society. Inspired by James Frazer (1894), John Swanton (1910), and Charles Seligman and Brenda Seligman (1911), Mauss formulates assumptions regarding the relation of Melanesian Papuan to the *potlatch* (1913), which will influence the views of anthropologists on exchanges in the Melanesian societies. Finally, the works of Marcel Granet (1920), Georges Davy (1920), and the materials delivered by Bronislaw Malinowski about the *kula* on the Trobriand Islands (1922) convince Mauss that something like a 'rock' (Mauss, 1999[1923/24]: 264) of all social practices exists in all of the known cultures. This 'rock' is the gift as universal principle of exchange leading to the peaceful association of the human beings through the mutual obligations to give, take, and return presents. What motivates the actors to do so?

There are two forces that Mauss describes using the Melanesian terms *mana* and *hau*. The *mana* is the force at the core of the magic and the religion which denotes the sacral character of the objects embedded in gifts (Firth, 1940: 483–510). The *hau* is the spirit of the giver belonging to the thing given which forces the return of the thing to its owner – an interpretation which will raise many controversies in ethnology (e.g., Lévi-Strauss, 1999: XXXVIII; Lefort, 1979[1950]: 1402; Weiner, 1985: 211–215; Firth *in* James and Allen, 1998: 23). Critics blame Mauss for not having interpreted the term *hau* correctly, and for postulating with the *mana* a mystical origin of human exchanges. According to Mauss, though, the *mana* and the *hau* are mythical expressions used by the Melanesian societies in order to describe the power of practical actions embedded in the gift. These actions are powerful because they regulate the entire society, i.e., they enable society to return to a balanced state where the power relationships as well as the properties are best distributed among the actors.

Mauss' gift is also at the origin of a more epistemological consideration regarding the nature of the social facts. Like the gifts reflecting all the facets of a society – domestic economy, religious ceremonies, festivities, the exchanges with foreign countries, diplomatic and power relationships, etc. – the social facts also crystallize this totality because they rest on gifts. The idea of totality is not an abstract one. On the contrary, totality means the material complexity of societies which enter the gift exchanges. These exchanges are vast systems of reciprocity which bind the human beings together within groups and societies. These lead Mauss to see in the gift a political ideal described in the conclusions of his essay. Mauss sees the gift as a mean to change the modern society making human beings more aware of their solidarity. While giving, one does not only give a present, but also gives oneself to the others. According to Mauss' conception of the gift, it is not a phenomenon specific to foreign societies and cultures. It is at the core of our societies which remains veiled by the rationalization and the individualism in modernity.

Mauss' gift stimulates many works in ethnology, cultural anthropology as well as in history, economy, philosophy, and sociology which gradually open the meanings of the gift, and tend to put in question the three obligations described by Mauss. With few exception regarding the critical considerations on Mauss' gift by Raymond Firth, Claude Lévi-Strauss, or Georges Bataille, most of these debates start in the early 1970s.

Reciprocity Instead of Obligations

In ethnology and cultural anthropology, the major works of Lévi-Strauss on the kinship structures and of Marshall Sahlins on exchanges take there starting point in Mauss' conception of the gift.

Lévi-Strauss and Sahlins criticize Mauss' global conception of the gift based on the sciences of religion. If the gift is important in ethnology and cultural anthropology, it is not because of the three obligations which Mauss uses in order to describe the kind of 'magical' power of the gift in regulating society. The gift shows us something more, i.e., the fundamental social link between us – reciprocity. According to Lévi-Strauss, reciprocity is the universal mental structure of human beings leading to exchanges and kinship (Lévi-Strauss, 1967: 100). These exchanges build the structure of society, and they rest on two main forms. There are restricted exchanges embedding two partners or a multiple of two, or generalized exchanges with far more partners (Lévi-Strauss, 1967: 159).

Sahlins operates in a similar way taking into account what Mauss describes as the system of total reciprocities made of the interrelations between the generalized, the balanced, and the negative reciprocities (Sahlins, 1972: 192–195). For Sahlins, these three reciprocities do not build a system. On the contrary, they form a continuum going from the extreme sociability (the generalized reciprocity) to the extreme unsociability (the negative reciprocity). Thus, the challenge of the gift is not to convince modern societies that they should rediscover these archaic structures of social life in order to empower societies with the obligations of the gift – in order to make it more solidary. It rather supposes, Sahlins suggests, that we examine how the reciprocity can be reproduced in our societies, a view which the contemporary literature on Mauss' gift will largely adopt (e.g., Case, 1976: 323–347; Price, 1978: 339–351; Weiner, 1980: 71–86).

The Gift as Expenditure and Scapegoats

Besides the structuralist cultural anthropology of Lévi-Strauss and Sahlins, the authors brought together around Roger Caillois and his *Collège de Sociologie* – a group of writers, ethnologists, and sociologists belonging to the surrealism built in the 1930s in France – also will return to Mauss' gift. Rather than to see in the gift the warranty of the social order, or the symbol of the reciprocal nature of human exchanges, they propose to consider it as revealing the irrational roots of societies and cultures. The works of Georges Bataille (1991) and René Girard (1986) particularly contribute to situate the gift within the framework of an economy of expenditure and sacral violence granted to the profit of society.

For Bataille, the gift is the symbol of a global economy primarily based on debts – because we are in debt toward the others and the natural environment in which we live, we have to give the gift. This does not erase our debts, rather on the contrary. It puts us in a cycle not of obligations, but of growing debts which lead to growing expenditure. According to Bataille, the gift symbolizes the structure underlying every economy which is in its essence an economy working on the basement of growing expenditures and debts which determine the development of our modern economy paradoxically pretending to be driven by the accumulation of profits.

Girard depicts a similar situation based on the often violent sacrifice of innocent actors described as 'scapegoats' which he finds out in every possible human society. Each society has to designate scapegoats who will be sacrificed, giving their life to the community in order for society to survive. According to Bataille and Girard, the existence of gifts shows that our economic and social structures are not resting on rationality. If gift has nothing to do with rationality, does it make sense to speak about the gift in a modern society dominated by the economic rationality and the financial transactions (Komter, 2005)?

The Gift as a Symbolic Market

Since the 1970s, the majority of authors consider against Bataille, Girard, and the surrealists of the *Collège de Sociologie* that the gift does not represent any irrational root of societies and cultures. On the contrary, it is a kind of exchange – in the broad sense of a social exchange, but also in a narrower sense of an economic exchange – whose rationality relies on the acquisition and the delivery of symbolic goods such as prestige values or altruistic qualities.

For this reason, Cheal (1988) and Camerer (1988) consider the gifts as a kind of economy which is not a market economy in a strict sense, but whose principles are similar to those of the market economy (Swedberg, 1990: 33). We offer and demand gifts, some gifts are carried out for altruistic reasons, others for egoistic ones (Stark, 1995). In this particular gift economy, the actors do not seek a material remuneration of their investment only. They also want to obtain a remuneration in a symbolic form – they want to be individually and socially upvalued by their gifts (Fehr and Gächter, 2000; Thomas and Worrall, 2002).

This symbolic rationality of the gift is at the origin of Pierre Bourdieu's ethnographical reflections on power relationships in North Africa. Bourdieu takes Mauss' gift into account in his description of gift exchanges in Kabylie (Bourdieu, 1972). After the work of René Maunier on the Kabyle *taoussa* (Maunier, 1927: 11–97) – a ceremonial exchange of money returned with interest – Bourdieu indicates that not only the *taoussa*, but every gift in Kabylie veils the power relationships between actors who do not have same economic and social capitals. According to Bourdieu, in the Kabyle society as in much of other ones, these power relationships are seldom apprehended as such. They remain dissimulated by the honor and the disinterest which the actors show when they exchange gifts. If there is any obligation to give in return, this obligation is never clarified, neither in person (who must give back?), nor in place

(where must the gift be returned?), nor in time (when must the gift be returned?). This is the reason why gifts are intrinsically ambiguous. They veil the interests of actors while exerting at the same time their honor and prestige. Everything looks like as if the Kabyle society refuses to face its own economic reality and social hierarchy in order to rather show them as controlled by laws depending on noble virtues. Hence, every gift rests on a spirit of calculation which is not different from the one expressed in the economic rationality of our societies. And as in our societies, the Kabyle actors spend a part of their efforts to systematically dissimulate this logic of interest and power which governs every exchange. In this sense, the gift is a mark of distinction between social groups bound to the affirmation of their nobility and social power.

The Gift as a Distinction Mark in Power Relationships

Parallel to economists and sociologists, several historians have also supported that gifts have always been distinction marks used in order to stabilize relationships of power within societies. Aristotle and Plato already depict gifts as associated as well with hospitality (Finley, 1988) as with the means by which the Greek tyrants establish diplomatic relations with their neighborhood (Van Der Mije, 1987: 241–267; Morris, 1986: 1–17). These exchanges of gifts also show up in societies with an important population and, for some of them, with a state. This appears more distinctively when we consider the history of gifts in the transition from classical antiquity to the Christian era. Paul Veyne, for instance, (Veyne, 1976) who writes on Roman cities in the time from 300 BC to AD 300 describes how they evolve from a use of the gifts restricted to the family members and the friends, to a use of gifts in broader circles, coming from the persons of rank in the city, and going to the population. Veyne calls these gifts *evergetism*, which is a neologism derived from the Greek terms *evergesia* and *evergetai*. The former means the desire to contribute to the well-being of the city. The latter depicts the civic attitude of benevolence of the persons of rank – the courtesy which Seneca describes as *beneficiis*. The *evergetism* secures the authority of the persons of rank in the city.

Peter Brown (1992) describes a similar phenomenon in the time from AD 300 to AD 450 regarding the relationship between the governors of the cities, their representatives, and the higher social classes. The honesty of the higher social classes toward the governors of the city and their representatives rests on the higher classes' expectation to have an impact on the political decisions using the patrician art of persuasion – the *paideia*. It is a benevolent way to influence them in order to make the political decisions following a noble art to rule the city. Brown indicates to which point the Christians govern this process using donations as the frame of the relationships between dominating and dominated social groups – for example, between rich and poor, or men and women – relationships which have been conceived similar to those toward God.

In the Dark Ages, the Renaissance and up to the French Revolution, gifts build the core of the relations between a population and its leaders. To give presents is associated with human qualities such as honesty or heroism, or with the grace (*gratia*) – which Raphaël represents in his painting 'The Three Graces' at the beginning of the sixteenth century. The grace remains an important societal topic at the end of the fifteenth century when the Spanish Kingdom stages Christopher Columbus' discovery of the American continent. The Amerindians and the objects brought back from America symbolize Columbus' power relationships to the Spanish monarchs (Vilches, 2004: 201–225). With the growing activities on economic markets, the donations are also often translated into amounts of money. If that does not make them loose their symbolic value – they symbolize the power, the honor, the reliability of relationships – these quantified donations nevertheless lead to a corresponding socioeconomic characterization of social groups (Howell, 2010). For example, if the European courts in the sixteenth and seventeenth centuries are willing to engage in more commercial activities, the nobility remains distant to economic exchanges not taking part in commercial activities in order to attest its social prestige. To the nobleman – the man of donation – goes the honor, to the tradesman and the salesman the money. This distinction is not a hermetic one because the tradesmen and the salesmen often solicit the nobility to get fortunate customers in order to make money (Kettering, 1993: 69–87). Nevertheless, the nobility claims for itself the gifts which are associated with the merit, the generosity, the honesty toward the monarchs who in return give them their grace to reward their loyalty. This relation of reciprocity and honor is for the nobility a confirmation of their social status, as well as a distinctive mark which makes them socially different from the upper- or middle-class rich *bourgeois gentillhomme*. The gift is, in this sense, against the modern economic market – a statement which will be brought to modern society in the 1980s by the interdisciplinary M.A.U.S.S. group around Alain Caillé (*Mouvement Anti-Utilitariste en Sciences Sociales – Anti-Utilitarian Movement in Social Sciences*).

The Gift against the Market Economy

Alain Caillé and the authors affiliated to his program – the M.A.U.S.S. – support the same consideration about the gift which is not irrational, but linked to honor, prestige, and nobility describing another kind of rationality. However, this rationality is not supported by any kind of calculation, and it is not the veil hiding the logic of interests transforming all of our social exchanges in power relationships. The gift does not describe another market economy. It supposes radical anti-utilitarian practices which are not compatible with the economy in the modern sense of this term (Caillé, 2000; Testart, 2001: 723; Anspach, 2002: 76). According to Caillé, antiutilitarianism is not only the radical criticism of the hegemony of economic rationality framing our daily life as well as the theoretical narratives of social sciences. It is not about to spend efforts and time in the solely critics of the economic semantics. It is rather a matter of delivering a perspective able to rank all social practices within the gift. The gift as a paradigm, so Caillé, is the reintegration of the market and the state in a social order made of gift exchanges which make sense for all social actors (Caillé, 1994). Pushed to the extreme, it is a cosmological principle and the axiom of the social theory, the origin of the unique paradigm which can be conceived and legitimated in the social sciences. In the framework of the

M.A.U.S.S., the gift consequently links to a wide range of contemporary problems, such as the donation of organs, sponsoring, technology transfers, build of civil associations, forms of national and international – governmental or nongovernmental – supports. As Mauss said, the gift is not an exotic character of the exchanges in foreign countries and cultures. It is at the heart of our modernity, and it represents the original structure of our social practices.

The Gift as an Impossible Exchange

In the 1980s, Jacques Derrida shows another position on the gift, assuming that, contrary to the thesis of the M.A.U.S.S. group, there cannot be any gift as a pure gift, and therefore, there is no possible gift. When we give something, we cannot give everything, we cannot give what belongs to us only, so that for Derrida, there is no gift in the strong acception of the term. The examples of time and death, his own ones and the ones of the others, lead Derrida to question the gift in the most radical way. If I can give the life or if I can kill others, I can neither live, nor die in their place, and I can neither give them eternity, nor immortality. It is the same regarding the gift. I can live the given, received, and returned gifts as events, but I cannot possess them. Even if I preserve a trace of them in me, this trace does not refer to these gifts, but only to me (Derrida, 1992: 47). Thus while giving, one can never be sure that the gift will be recognized by others as such. Therefore, it is unsure that the others receive it, return it, or give it further. The obligation, the duty which makes the circulation of the gifts happened only refers to the 'I' of the giver. He is responsible for the gift, and he cannot delegate his responsibility to others without being at the same time irresponsible. He cannot give without doing at the same time an irresponsible act leading to the negation of himself as 'I,' as the legitimated identity of the giver, without denying the gift. When he does it, then giving the gift turns into calculation which destroys the value of what is given and the act itself (Derrida, 1992: 104). Giving cancels the gift and makes it impossible.

Jean-Luc Nancy avoids this extreme conclusion while following a similar path to the one of Derrida. Derrida shows that the absolute gift does not exist. But it does not mean that the gift is not possible. One can even benefit from the criticism of Derrida in order to investigate how, if the gift cannot exist as an absolute gift, the phenomena occur in our daily life, that we name 'gift.' Taking this into account, we can then put an end to the myth of a pure gift (Nancy, 1988: 33), and we can also manage to deconstruct – as Marcel Hénaff proposes it – the relationships between gifts and economic exchanges which, as Hénaff suggests, maybe never have been bound together (Hénaff, 2002).

The Gift as an Ethnocentric and (Post)colonial Scheme

Derrida's deconstruction of the gift has also ramifications to very different theories supported by antiglobalization authors like Serge Latouche. Since 1990, Latouche casts doubts on the viability of a social theory using the gift (Latouche, 1998: 311–322). In all noncapitalist societies in the world, there is no true gift because there is nothing truly free, since nothing has to be paid. At the opposite, where one must pay for goods and services and where it is normal to do so, where the capitalist economic system pertains to almost all cultures and to all facets of the social life, there are gifts of various forms. Thus, the gift is not a strong paradigm – it is a Western phenomenon with the help of which one tries to ennoble and excuse the violence of the capitalist economy. Who defends the gift defends a (post)colonial kind of ideology linked to the market economy of industrialized societies. All in all, there is no viable alternative to capitalism apart from a firmly antiglobalization attitude. It can lead to give up helping countries in need of economic and technological support like Third World countries. But this attitude must favor their autonomous development. If another world is possible, it comes from the world of the others and not from our societies. The only thing which our societies must make is to express their solidarity while decreasing their life standards at the same level as the ones of these countries (Latouche, 2003: 18–19). The gift is dead, long live the gift!

Conclusion

Between economy and society, freedom and constraint, gratuity and interest, us and the others, the gift is a multiform and deeply ambivalent concept as early noted by Emile Benveniste regarding the ancient Anatolian verb *da* (Benveniste, 1966 [1951]: 315–327). The conclusions drawn from the first analyses on the gift show it – in proximity with Karl Polanyi (1944) and Alvin Gouldner (1960: 161–178) – as the point where morals and economy converge, and as the rock of all human exchanges. The contemporary analyses of the gift have deconstructed these certainties. Without denying the interest of the researches on the gift, they tend to relativize its obligatory and reciprocal characters, and they criticize the link between the gift and the idea of a morally viable social economy in industrialized societies. Is the gift carrying the fundamental standards of our exchanges? Or does the gift only show our blind idealization of these standards, unveiling our ethnocentrism when it comes to analyze the various features of social and cultural exchanges? These questions are likely to find neither an immediate, nor a final answer. Nevertheless, they contribute to underline a vast field of interdisciplinary problems which the history of the gift echoes while prolonging the reflections on the gift, namely that of the transformations of the forms of our exchanges in the history and through the cultures.

Abstract

The Global Agenda for Social Work and Social Development (*The Agenda*) is being developed by three global, professional organizations – International Association of Schools of Social Work, International Council on Social Welfare, and International Federation of Social Workers. Launched in 2010 to strengthen the international profile of social work and social development, it enables social workers to make a stronger contribution to policy development. *The Agenda* identifies four fields for action by global institutions, local communities, and the three organizations: promoting social and economic equalities, promoting dignity and worth of peoples, working toward environmental sustainability, and strengthening human relationships. This article links *The Agenda* process with parallel developments within the worldwide social work professional community.

The Global Agenda for Social Work and Social Development (*The Agenda*) is being developed and promoted jointly by the International Association of Schools of Social Work (IASSW), the International Council on Social Welfare (ICSW), and the International Federation of Social Workers (IFSW) (Jones and Truell, 2012). It is designed explicitly to strengthen the profile and visibility of social work and social development, to help these organizations to acquire new partnerships, to boost the confidence of social workers, and to enable social workers to make a stronger contribution to policy development. *The Agenda*, as a document and a process, is responding to increased social complexity. It is designed to reposition the global social work professional community, together with social development professionals, as a core source of information about social problems and of creative responses to these. The aim is to ensure that the experience and skills of social professionals are recognized and applied to achieve sustainable, collaborative outcomes drawing on the acknowledged skills of social workers in creating multifaceted, pragmatic solutions to highly complex problems, both individual and social (e.g., see Sucharipa, unpublished; Sweifach et al., 2010; Dominelli, 2012).

The mission of the social work profession and the development of social policy are rooted in a set of core values (International Federation of Social Workers and International Association of Schools of Social Work, 2004). These core values, embraced by social workers, social work educators and social development practitioners, are the foundation of social work's unique purpose and perspective (Hugman, 1995; Chan, 2000; Banks and Nøhr, 2011). That perspective has its foundations in the frontline work of social workers, whose task is to respond to some of the most complex individual, family, and community challenges. There are many causes behind human problems, but they always involve an interweaving of personal and social factors. The development of the Global Agenda gives the opportunity to build upon past experiences and to articulate a new and crucial vision for engagement that can mobilize social workers, their representative organizations and their partners in the new global context.

Global Context

The worldwide recession, globalization of economic systems, heightened inequality within and between nations, extensive migratory movements, increased pandemics, climate change, natural catastrophes and new forms of conflict, compel social work practitioners, educators, and social development professionals to find new ways of responding to new realities (International Federation of Social Workers, 2004; Jones et al., 2004).

The impact of global crises has been generally acknowledged, for example, in the United Nations report 'The Global Social Crisis' (United Nations Department for Economic and Social Affairs, 2011) reflecting concerns identified in the report of the World Commission on the Social Dimension of Globalization (2004). This context was addressed in the foreword to the 2011 report by Sha Zukang (former Under Secretary General, Department of Economic and Social Affairs, United Nations and keynote speaker at the Hong Kong world social work conference 2010). He stated that it is essential for governments to "take into account the likely social implications of their economic policies. It has been shown time and again that economic policies considered in isolation from their social outcomes can have dire consequences for poverty, employment, nutrition, health and education, which, in turn, adversely affect long-term sustainable development" (United Nations Department for Economic and Social Affairs, 2011: p. iv). The Report also found that many governments did not pay enough attention to the social implications of the recent global financial crisis and urged that social investments be given priority in recovery programs.

Given this global context, the challenge for social work and social development is how best to build effective linkages between the global realities and the local community response (Pettifor, 2004; Lyons et al., 2006; Payne and Askeland, 2008; Healy and Link, 2011).

Geopolitical, social, and economic shifts also have their impact on social work and social policy. The predominance of western theories and practices is being challenged by articulate

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28035-5

practitioners and educators in the global south, creating lively philosophical and practical exchanges (see, e.g., Yip, 2004; Cox and Pawar, 2006; Netto, 2006; Brazilian Centre for Cooperation and Exchange of Social Services (CBCISS), 2008; Laird, 2008; Law and Gu, 2008; Hatta, 2009; Mwansa, 2010; Nikku, 2010; Ofreneoa, 2010; Rankopo and Osei-Hwedie, 2011; Truell, 2011; Abdullah, 2013).

Organizational Context

This Agenda is the product of a collaborative initiative undertaken by three international organizations representing social work practice, social work education, and social development. These international bodies grew out of the world social service conference in Paris in 1928 and have formal consultative status with the UN Economic and Social Council and other UN and related agencies.

The IASSW is an international community of schools and educators in social work, promoting quality education, training and research in the theory and practice of social work, administration of social services, and formulation of social policies. IASSW speaks on behalf of 2000 schools of social work including 500 000 students.

The ICSW is a global, nongovernmental organization which represents tens of thousands of organizations around the world that are actively involved in programs to promote social welfare, social development, and social justice.

The IFSW is the global federation of national social work organizations representing 100 countries with over one million social workers.

The three organizations have cooperated more or less closely over the 80 or more years of their existence. They jointly own the journal *International Social Work* and have organized several joint conferences regionally and globally. IASSW and IFSW have jointly published the Global Definition of Social Work (currently under review) (International Federation of Social Workers and International Association of Schools of Social Work, 2001), the statement of ethical principles (International Federation of Social Workers and International Association of Schools of Social Work, 2004), and the Global Standards for the Education and Training of the Social Work Profession (International Association of Schools of Social Work and International Federation of Social Workers, 2004). In the current context, they recognize the professional and organizational value of sharing strategy and common purpose. They recognize the need to link social work education and practice and sustainable social development into a single collaboration. They are also committed to promoting wider partnerships, such as the links with the Social Work Health Inequalities Network (Bywaters et al., 2009; Fish and Karban, 2013) and the Commonwealth Organization for Social Work, as well as with service user organizations.

History of the Agenda

The Agenda process started in 2004, arising from a series of parallel developments in the three global bodies. The IFSW Executive agreed that the Federation needed to develop strategies to provide clearer professional leadership in response to the changing social context and evidence of world-wide low morale and loss of confidence felt by social worker practitioners (Stevens and Higgins, 2002; Jones, 2005; Depanfilis and Zlotnik, 2008; Vyas and Luk, 2011). At the same time, IASSW was exploring strategies for increasing global influence and ICSW was changing the relationship between global conferences and its advocacy strategy. To pursue each of these goals, the three organizations had decided to hold joint world conferences and started planning a major conference in Hong Kong in 2010. Building global partnerships and planning global conferences take time, involving internal democratic processes and relationship building.

Having made the agreement, the three organizations sustained the commitment and gradually developed plans and a shared analysis. The 2010 conference program was shaped to support the development of a world social agenda and the three organizations began examining how the process could be supported and sustained.

Background papers were commissioned and published on the website (see IFSW website) and existing partnerships with UN and other bodies were used to explore the evolving ideas. Members and organizations were invited to examine the papers and to come prepared to participate in the strategic developments. The organizations consulted with social workers, social work educators, and social development practitioners.

When *The Agenda for Social Work and Social Development* process started in 2004, it had not been envisaged that the initiative would be launched in a time of major financial and social crisis. When around 3000 social work practitioners, educators, social development professionals, and policy makers came together in the Hong Kong 2010 world conference (see conference website) the new global economic and social reality was becoming clear and the need for shared action seemed even more necessary and urgent. Rapporteurs collated ideas emerging from the conference workshops and presented the outcomes in the closing session. The three Global Rapporteurs drew the elements together and, working with the three Global Presidents, presented themes and strategies to the closing session.

The following four pillars of *The Agenda* emerged and were endorsed:

- promoting social and economic equalities,
- ensuring the dignity and worth of the person,
- promoting sustainable communities and environmentally sensitive development, and
- promoting well-being through sustainable human relationships.

This formulation was a minor refinement of the four pillars which emerged in Hong Kong and was agreed at the Accra meeting in 2011. A commitment to ensuring an appropriate environment for practice and education was added later. The *Global Agenda* received overwhelming support from delegates, who supported the launch of a global movement led by IASSW, ICSW, and IFSW.

The preamble to *The Agenda* which emerged from this process stated its aims as "developing multiple platforms to foster the emergence of a Global Agenda for the profession

through the shared, collective voice of its members." The shared intention was to engage the conference participants and those not able to attend in a new form of dialog which would identify agreed priorities and shape the action plans of each organization. This was recognized as an ambitious and daring process, with significant risks, but the conference evaluation showed that it had succeeded.

The three founding organizations represent only the beginning of the collaboration. It is intended that further alliances will be built with likeminded movements to maximize the impact of creating positive social change. It is recognized that such change will be most likely to occur when common strategies link *The Global Agenda* with regional and national priorities.

Following the conference, the text of *The Agenda* and the supporting documents and action plans were posted on the website and widely distributed throughout the organizations. The core themes identified by the 3000 participants in Hong Kong were subject to extensive, global debate and feedback, in particular widespread debates in schools of social work and social work agencies on World Social Work Day 2011. The responses broadly endorsed the four priority areas.

The final round of postconference consultation culminated in a tripartite meeting in Ghana in November 2011, which focused on actions needed by each organization and the partnership to ensure a strategic focus on the four priority areas, resulting in a renewed determination to promote social work and social justice. The representatives agreed that:

- the full range of human rights is available to only a minority of the world's population;
- unjust and poorly regulated economic systems, driven by unaccountable market forces, together with noncompliance with international standards for labor conditions and a lack of corporate social responsibility, have damaged the health and well-being of peoples and communities, causing poverty and growing inequality;
- cultural diversity and the right to self-expression facilitate a more satisfactory intellectual, emotional, moral, and spiritual existence, but these rights are in danger due to aspects of globalization which standardize and marginalize peoples, with especially damaging consequences for indigenous and first nation peoples;
- people live in communities and thrive in the context of supportive relationships, which are being eroded by dominant economic, political and social forces;
- people's health and well-being suffer as a result of inequalities and unsustainable environments related to climate change, pollutants, war, natural disasters, and violence to which there are inadequate international responses.

Recognizing these realities, the representatives formulated key objectives related to each of the four key themes of *The Agenda* which had been agreed in Hong Kong (see above). Each theme targets commitments to three areas. The first set of commitments focuses our joint activities on presenting a social work and social development perspective in our work at the United Nations and other international agencies. The second set of commitments recognizes the importance of strong and resilient communities to achieve stable well-being and the importance of the role of social work and social development practitioners in facilitating healthy and strong communities. The third set of commitments relates to the internal activities of our own organizations, directed toward ensuring that policies and standards are consistent with addressing the root causes of poverty and oppression and promoting sustainable social environments which make a reality of respect for human rights and dignity. Finally, the platform recognized the significance of education and training and of the working environment for effective and ethical social work practice, and includes commitments to coordinate research and activity to improve these elements.

The Global Agenda for Social Work and Social Development: Commitment to Action was formally released in the week of World Social Work Day and UN Social Work Day in March 2012 (International Federation of Social Workers et al., 2012) at simultaneous events in Geneva and New York.

The Agenda was received on behalf of the United Nations by Helen Clark (Head of the United Nations Development Program). She commented:

> It is an honour for me to accept the Global Agenda for Social Work and Social Development on behalf of the UN, and to congratulate the International Federation of Social Workers, the International Association of Schools of Social Work, and the International Council on Social Welfare on developing The Agenda.
>
> I understand that the Global Agenda was adopted with the overwhelming support of delegates to the joint conference of your three organisations in Hong Kong. That suggests that there is a widely shared and clear vision across the international social worker community, which gives the Global Agenda great credibility…
>
> We too are pledged to address the root causes of poverty, oppression, and inequality. We support the call in the Global Agenda "to create a more socially-just and fair world which we will be proud to leave to future generations"…
>
> For more than a century, the social work profession has been at the forefront of promoting human rights and supporting people to realize their full potential. Various arms of the United Nations have worked with your organisations in global fora, and alongside social workers in-country to advance progress on the Millennium Development Goals, engage citizens in development, and strengthen social protection systems…
>
> …the formal presentation of your Global Agenda also reminds us of the shared vision and values we have, and of the importance of working together for a better world. (Clark, 2012)

The Agenda was also received in the Geneva office of the United Nations by Assane Diop, International Labour Organisation (ILO) Executive Director. He referred specifically to the Social Protection Floor (SPF) Initiative and said that large numbers of social workers and social development workers were needed to help:

> Create the political will to build the Social Protection Floor
>
> Create public awareness about the need for the social protection floor, and
>
> Design, implement and monitor the Social Protection Floor. (Diop, 2012)

Mr Diop said there was "formidable support for the mandate of the Global Agenda" in the United Nations. He

further said that social protection in all aspects of social and economic life was a necessity for all people to live in dignity and that the SPF should be visible in all the countries of the world.

The Agenda has also been received by the United Nations in Nairobi, Santiago de Chile and Bangkok and by a number of international bodies including the African Union, Commonwealth Foundation, Council of Europe, and Social Platform of NGOs in Europe.

The Stockholm Joint World conference in July 2012, commissioned by IFSW, IASSW, and ICSW, enabled participants to focus on implementation of *The Agenda* and strategies for action (see conference website). The three Presidents, in separate speeches on behalf of the three organizations, restated the commitment to joint work on *The Agenda* and to monitor its implementation.

The next stage of the implementation strategy includes a commitment to launch and promote a Global Observatory, drawing from a global network of regional centers, to support implementation of *The Agenda*, research its impact and study the work environments which promote positive outcomes in social work and social development. The plans for the Observatory were agreed at a tripartite meeting in Paris in November 2012 and launched in January 2013. The Observatory will present its first report to the 2014 world conference in Melbourne, drawing on regional and national reports, focusing on the first Agenda theme – promoting social and economic equality. This theme is also the focus of World Social Work Days in March 2013 and 2014. The report will be published, to coincide with the conference, as a supplement to a special issue of International Social Work which will include papers on social and economic development.

The Impact of the Agenda on the Social Work Profession

The objectives set out in *The Agenda* are having and will continue to have far reaching implications for the social work profession. Each of the five objective areas of *The Agenda* specifies that each organization will adjust its policies, and other official documents, to ensure they are consistent with *The Agenda*.

IFSW, for example, is undergoing strategic change as *The Agenda* evolves the professional focus and culture of international social work. This is in part due to the outward looking nature of *The Agenda*, with a strategic commitment to use new media, to consult and involve social workers, to plan and coordinate global activity more effectively, and to engage systematically with UN agencies and other partners. Whilst the Federation has had many past successes working with others to influence global policy statements, such as the UN Declaration on Indigenous Peoples and work on extreme poverty and human rights, there has not been an overarching policy framework and strategy. In practice, the international profession has tended to be more focused on developing the identity and professional status of social work at global level. This was demonstrated in the official Aims of the Federation, which stressed the establishment of national organizations of social workers and bringing the organizations together for the exchange of ideas and the formulation of polices.

The Agenda objectives clearly indicate a new set of political intentions for the three global organizations. The strategy more explicitly focuses on changing the dynamics that affect the people who use social work services, as demonstrated in *The Agenda* commitments document:

> We commit ourselves to supporting, influencing and enabling structures and systems that allow people to have power over their own lives.
>
> We commit ourselves to supporting, influencing and enabling structures and systems that positively address the root causes of oppression and inequality.
>
> We commit ourselves wholeheartedly and urgently to work together, with people who use services and with others who share our objectives and aspirations, to create a more socially-just and fair world that we will be proud to leave to future generations.

The Influence of the Agenda on Global Policies

The Agenda compels social work professional organizations and social workers to advocate a social work perspective in the political systems that affect the well-being of their clients. For example, writing in *International Social Work*, Truell (2012) called for changes to the trade system to regulate economic activity, in the context of reflections on the Occupy demonstrations:

> Through The Agenda Commitments (2011), The International Federation of Social Workers (IFSW), The International Association of Schools of Social Work (IASSW) and The International Council on Social Welfare (ICSW) supports the International Labour Organization's call for international standards to regulate the global workforce conditions and trade arrangements to create a socially just and sustainable global economy. …Socially-just global economic frameworks would be based on: human rights, fair pricing, international standards of labor conditions, corporate social responsibility, capacity building, agreed forms of dialogue underpinning supply and demand agreements – enabling all parties to participate, and enhancing communal rights and benefit sharing. (Truell, 2012: p. 593)

Another example of the impact of *The Agenda* is seen in the IFSW announcement of a conference in South Africa that will 'give voice to peoples who are targeted by social development policies and for their voices to influence the policy development frameworks' (see conference website). The conference scheduled for 2013 was planned to influence the policies and structures that will replace the UN Millennium Development Goals when they expire in 2015.

The Agenda partners have also been actively influencing the United Nations by issuing joint statements through their formal consultative status. One such example is a statement on *social and human rights questions: social development* (International Association of Schools of Social

Work and International Federation of Social Workers, 2012):

> As Social Workers, Educators and Social Development practitioners we witness the daily realities of people living in poverty and the multiple systems that alleviate hunger, ill health and exploitation. We therefore make the following statement to UN member-states that are responding to their people living in poverty and to member-states that benefit from the exploitation of impoverished countries. 1, People cannot be developed and managed by others: Our frontline experience has taught us that to escape from poverty people need to be actively involved in their own futures. They need to be able to contribute to best practice ideas, and as leaders, they need to be able to form collaborative engagements with funding bodies, managers of resources and other systems for support. 2, Basic minimum levels of social protection: As global bodies representing international social work and social development we know that poverty is worst where there are no social protection systems covering the lifespan. We support the UN's call for a minimum social protection floor to be built in every country. 3, Poverty eradication through systemic responsibility: As social workers and social development practitioners we understand that in many instances poverty is sustained through exploitive systems. We advocate for trade systems to be based on human rights, fair pricing, international standards of labor conditions, corporate social responsibility, capacity building, agreed forms of dialogue underpinning supply and demand agreements – enabling all parties to participate, and benefit sharing.
>
> We, as frontline workers, social work educators and members of affected communities commit ourselves to assist in bridging the links between people living in poverty, national governments, regional authorities and international frameworks. We welcome working with UN member-states and the UN agencies to fulfill the vision of eradicating poverty and fulfilling the MDGs.

Another regional example of translating the objectives of *The Agenda* into political advocacy was the Statement on Austerity submitted by IFSW to the European Union in 2013 jointly with the IFSW member organizations living through the negative effects of austerity (International Federation of Social Workers, 2013). This statement highlighted the need to ensure people's well-being was not subject to the whims of the economic market:

> This is not a crisis of the Euro; it is a crisis for people. The EU's market driven strategy of pursuing 'austerity' and 'competition' is not producing the anticipated 'growth'. Instead it is producing entrenched poverty, placing the peoples of the affected countries at risk of civil violence, and critically undermining the possibilities for rebuilding the affected societies.
>
> The EU directions are driving massive job losses, price increases, economic/social and personal depression, loss of the skilled workforce, business failure and increased inequality. Further, as people have lost access to adequate housing, health and education services critical problems are multiplying and will have lasting implications for the future generations. Such environments, as expected, have seen the significant growth of extreme right wing political parties/organizations that attack the vulnerable, disabled and immigrants, and hold the potential to destabilize democratic processes.
>
> As international professionals who see the results of both strong and weak communities and societal structures, we witness that resourced and confident communities are the cornerstone of a stable and thriving economy. Businesses want to operate in environments where the workforce is skilled, secure and reliable and there is sustainable demand from consumers. We therefore call upon the EU to abandon austerity and free market approaches and urgently to introduce new processes that bring the affected parties together to establish long-term and planned solutions, which emphasize: People living in coherent, stable and equitable environments, and sustainable economies.

Concluding Remarks: Building Capacity and Impact

The 2014 Global Observatory report will be a significant landmark for the three organizations and global social work and social development. This first global report will consolidate *The Agenda* strategy and provide new avenues for interacting with the United Nations and other global policy bodies. It is envisaged that the biannual reports will increase in significance, not only within the social work community but also in wider social policy arenas. To achieve this ambitious objective, a more robust infrastructure needs to be developed; discussions are beginning on funding for a global observatory structure which will be owned by the three organizations, with the potential to involve new partners.

The process of developing *The Global Agenda* has re-established the connection between the practice of social work, wherever that might be in the world, the education of social workers and the development of social policy at national, regional, and global levels. Making statements on social policy is not new for international social work organizations, but *The Agenda* platform, which was developed by social workers throughout the world, gives new energy and commitment for taking such political positions, with and alongside the people who use social work services. *The Agenda* represents the beginning of a long-term commitment to advocate for new social systems that address the root causes of poverty and oppression and to challenge the social forces which erode personal well-being. It is recognized that many more policies and action platforms, underpinned by the values of social work, will be needed to ensure that *The Agenda* has impact in daily practice and on the education and training of tomorrow's social workers.

Acknowledgments

The authors acknowledge the contributions of the Joint Coordinators of The Global Agenda process – Abye Tassé with Lena Dominelli (IASSW) and Charles Abbey with Sergei Zelenev (ICSW) and, the Presidents and other colleagues from the three global organizations.

Global Development: Markets and Wellbeing

Alberto Arce, Wageningen University and Research Centre, Wageningen, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The relationship among global development, markets, and well-being is an important theoretical and methodological association to address and analyze theoretical ways of 'value framing and talking' among experts, institutions, and people. These relations may take the forms of interfaces, dislocations, and disjunctions, which are expressed under the notion of 'new materialities', encompassing the encounter of social and biological sciences. Main social concerns still are civic manifestations, knowledge encounters, and policy dilemmas present on contemporary global modernities. This interrelatedness of concepts, ethnography studies, and imagined spaces represents a cosmopolitan configuration that focus on the reflexivity of development studies and direct us to critically reconsider dualistic ways of thinking about the world. Today actors involve themselves arduous laboring of becoming engaged in development processes through social action to organize and materialize their meaning, values, and new subjectivities, as an expectation of becoming 'new' social actors. This orientation reaches the core of the anthropology of development endeavor.

Introduction

Conceptually, global development is an important representational site in which the meaning and intent of governance and development policies can be critically grasped and analyzed. The language of 'good government' and 'the market' (Stirrat, 1992) is one instance of this representation. During the 1990s, official discourses equated markets with democracy and heralded this relationship as part of a contemporary cosmopolitan configuration of empowerment; one based on market forces and consumer choice as a source of social inspiration to construct a new subjectivity – the enterprise spirit – that could shape the identity and economic relevance of social groups.

Well-being studies have encompassed the importance of material and nonmaterial resources in processes of development (Gough and McGregor, 2007). This orientation reaches to the core of the anthropology of development endeavor: Equal attribution to the importance of material and nonmaterial aspects of social life invigorates understanding of how people's experiences reflect a fast changing world. This permits explanation of how actors' expectations and struggles to attain development and overcome poverty are achieved. This orientation focuses on questions of reflexivity in development studies, including the researcher's own encounters and experiences with the lifeworlds of actors in the development arena. Recognizing that there are some actors wishing to reshape and others to contest policy measures that threaten the livelihood or human rights of human populations around the world provides the possibility of constructing ethnographies that are concerned with the depiction of particular actions and values (Graeber, 2001) for territorializing and reterritorializing elements of multiple 'modernities and traditions'.

This article takes a broad view of what constitutes the theoretical and methodological *bearings* of the association of global development, markets, and well-being. This relation is seen as centrally connected to theoretical ways of talking about the manifestations and dilemmas of contemporary global modernities (Arce and Long, 2000). The frequent emphasis placed on the interaction between discourse and social action in texts that explore the makeup of globalization processes and local responses can be traced to the contribution of Giddens' theory of structuration (1979, 1984) and to his conceptualization of structure and agency and to how this shapes, and is itself shaped by, 'modern' social and individual life (1990).

This theoretical orientation facilitated the counterrepresentation of various forms of 'modern economic development' as freedom (Sen, 1999) and to appreciate the capability for actors to perform the lives that they themselves value (Long, 2001). This has brought to the fore new ways of framing how actors are enacting the mainstream economic political development and institutional challenges. This directed anthropology to interrogate modes of intervention (Mosse, 2005) and civic participation (Foweraker, 2001; Fox, 2007; Arce, 2010), this clearly ensure the critical depiction of the advance of democratic values (Paley, 2002) and rights (Merry and Goodale, 2007). As 'world audiences' interests lead to an increasing interrelatedness of global development, markets, and well-being, since the end of the 1990s, actors started to perform actions to meet a wide-range of basic needs. These actions became socially relevant, as civic participation came to equal the importance of global developments and markets (Carrier, 1997). These contemporary associations challenged lineal cause-effect methodologies to explain processes of development and extend the significance and 'language' of markets to rethink types of development and poverty.

Our concern here is with the conditions of possibilities for the democratization of research about global development in the context of an ethnographic methodology, critically engaged with academic and policy dominant orientations, especially those organized by the social sciences in the West (Appadurai, 2003). Thus, there is a need for researchers to rethink critically the nature of anthropological studies in a global era, and the kind of contributions that anthropology of development can make to actors and their well-being.

Methodological Encounters and Tribulations

A glimpse at the contemporary literature on development and social change indicates that development subjects are not a mechanical outcome of apparently objective circumstances. That is the global associations between events apart in space and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10152-7

adjacent in time are uneven, fragile, and heterogeneous in contemporary social change. People living in different zones have come to realize that the world and their zones are not unified systems. These zones cannot be controlled and administered by stationary technologies, the conservation and protection of classical styles of organization, the domestic shelter of economic activities, the regulation of transformations in the international markets, and the use of new large-scale mediation policies among international, national, and regional contexts.

In their attempts at interpreting these global developments, social scientists have recognized these new range of conditions, uncertainties, and sociopolitical responses. And in this manner, states, transnationals, markets, technologies, and global entities themselves enter (in deterritorialized and territorialized forms) actors' zones, where the reordering of social processes is taking place. This generates conflict and negotiations. However, this reality is quite different from reports of global conflict on Internet media and television. Hence, these parallel sets of global representations of people, conflicts, and 'realities' introduce a high degree of tension in individual actors 'global consciousness' and their sense of multiple world realities (Beck and Grande, 2010).

Underpinning the description and analysis of these encounters are methodological advancements over disciplinary concerns (Rabinow et al., 2008). These have come to be recognized as the implicit sociopolitical characteristics of science and technology is continually generating new discourses that are demanding new accounts of agency and practices implicated in a complex field of relationships that may take us to think afresh notions of development, markets, and well-being. The recent surge in interests of matter and material experience (Coole and Frost, 2010) contributes to reshape the development field, as an activity rather than just a ground for representations and it has yielded a varied and colorful mosaic of ethnographic fieldwork experiences, directing us to reconsider dualistic ways of thinking about the world. Hence an anthropology of development rests on the malleable boundaries between social anthropology and sociology in an attempt to work together with natural science fields, such as agriculture, climate, ecology, and nutrition.

The inspiration of the new materiality issues has resonance with a renewed emphasis on the value of ethnography and a contribution to a relevant agenda for an anthropology of development. Our focus on development is characterized by both 'outside' intervention and 'inside' creativity. This perspective orients us to consider development interactions, as an assemblage (Ong and Collier, 2005) of socioeconomic, cultural, environmental, and biological conditions and an engagement with the new cosmopolitanism (Werbner, 2008), rather than a priority with the physicality of emerging processes, enabling the presence of global and localized discourses to exteriorize social forms of contemporary 'material realities'. The challenge is then how to approach analytically these entities and 'new' realities (De Landa, 2009).

Entities and Actors' Subjectivities

The existence of entities and realities (global development, markets, and well-being) are repositioning and reshaping actors' subjectivities. Some of these are presented as new political alliances between science and the social (Coole and Frost, 2010; De Landa, 2009). Others, introduced as innovative forms of capitalist coordination, are carving indenture pockets of control across physical distances, while dispossessing people by the privatization of public assets (Harvey, 2003). These associations are displayed as new and flexible development strategies of 'mature' capitalism, but also these are seen as a manifestation of forms of contemporary managerial failure. The inability to control agency in the functioning of a fluid world of various flows and ebbs of discourses, people, objects, and images is turning around values and the material world, repositioning, commodities, people's identities and the material organization of the world, precipitating various kinds of actions, interactions, performances, and enactments.

One of these entities is quality. This sort of entity which occurs around social relations is generating contests among public, private, and markets goals. Quality is and emergent entity around the creation of new spaces that affect actors' feelings and emotions. The intensification of commoditization (Scheper-Hughes, 2005) attached emotions of lost security, justice, and fairness to 'pure reason' searching for economic profitability and we are witness to new an unexpected assemblage of everyday life.

The recent concern in social research with consumer awareness of food risk has added a social relevance impetus to the notion of quality. The apparent reduction of quality in modern food has generated a significant body of critical research on the growth of alternative food markets. As consumer reaction to industrialized food circuits has increased, fears over contamination have risen, as have concerns over social justice and environmental sustainability (Kloppenburg et al., 2000; Allen et al., 2003; Trauger, 2007). Modern convenient products may imply industrial and chemical food processing accompanied by impacts on the rise of non-communicable diseases (NCDs), such as those associated with food and nutrition, contamination, and the environment. Despite a growing consensus on the global rise of obesity and concerns over future health consequences, such as cardiovascular diseases and diabetes, there is far less international agreement on the appropriate public policy response.

This is an example that highlights consumer concerns, however, these would be deficient if an appreciation of entities such as quality are missing from an understanding how these markets' 'fears' have resulted in a 'real' and 'fragile' world for consumers, where commodities are enabling insecurity and may reduce the well-being of individuals' health. In the absence of suitable market conditions for quality food consumption, the formulation of quality standards is seen as the only way forwards; a governance device to promote diverse and at times contradictory sets of scientific, social, ethical, and policy issues. These are bureaucratic and hierarchical attempts to manage and control assemblages of resources, commodities, and people's demands for food. The recognition that a consumer stunted by malnutrition or able to eat in excess, particularly 'modern' foods to an undesirable state of obesity, both are part of emerging materialities clustered as the field of NCDs. These diseases are starting to be recognized, as reducing the potential of people for development and centrally important in decreasing actors' well-being – quality of life – in a physical

sense. These materialities are molded from a world surrounded by constant ambiguity and in continuous institutional conflicts, which blur existing private and public boundaries for policy intervention and individual/collective creativity. This proposes to reconceptualize previous notions of agency across social, cultural, and natural actual characteristics of development to explain variations in external factors, such as income, work, education, community, governance, values, religion, and political factors in personal choices, such as the access to food quality consumption.

However, the food quality is not a puzzle to be solved exclusively through private-voluntary standards and public policy, but a heavily contested, often chaotic field characterized by high rates of uncertainty and vulnerable to competing beliefs and ideals over well-being desirabilities. It also is an expression of people's agency in mobilizing public policy, ideas about needs, potential desires, which are reasonable for family-level purposes within which an individual is born and lives. This agency interacts with the increasingly 'bads' of modernization and development, conditioning many aspects of both the birth of civic counteractivity, in the form of growing and diversifying food movements, and the individual improvement of expectations about his or her quality of life. These ranges of civic movements and individuals' expectations along with a spectrum from a country or region with indigenous populations recovering their food heritage to an industrialized country with a rural population producing organically and locally, it has over time shifted well-being concerns from the agronomy of food production to processes of food circulation and consumption, thereby forging new, more nuanced understandings and practices in ecology, economy, and health.

Countries and their people are trying to adjust to changing needs within the increasing mobile global market places. Thus, the market is a key site through which producers and consumers are expressing and pursuing their experiences and understanding of well-being, as the multidimensionality of life that includes physical health and safety, community and family social relations. Actors are striving to actively define and improve the notion of well-being. They involve themselves in the arduous laboring of becoming engaged in development processes through social action to organize and materialize their meaning, values, and new subjectivities, as an expectation of becoming 'new' social actors.

New Subjectivities: The Consumer–Citizen in Ecuador and Beyond?

Bekkering (2011) presented a group of food basket housewives that she described as consumer–citizens, and the 'ultimate expression of care', both in term of cooking and food provision, as well as meaningful participation in family community social relations. This case from Ecuador shows these experiences have begun to address concerns over the changing of subjectivities, which are triggered by feeling of social justice and environmental concerns associated with food production, the mainstream market, and its food provision chains. One of the achievements of the food movement is the establishment of a shopping routine that is subsequently carried into 'good' eating practices. Members of the food basket obtain fresh products for discount prices and the meeting themselves are opportunities to socialize consumer experiences as well as to network around emerging ideas and opportunities, such as short-term employment or the cleaning up of a local playground for their youth. The development of a more 'responsible' shopping routine has done much to continue the consumption of whole, home-cooked meals that are generally quite healthy. Organization around 'good food' to counteract the surge of obesity represents a tangible, civic political outcome, and highlights the potential of new subjectivities and social relationships. The food basket experience represents a source of citizenship empowerment for low to middle-class families in improving the household budget and procuring environmental safer, healthier food for a segment of Ecuadorian society (Sherwood et al., 2013).

In order to comprehend the magnitude of these social transformations under way, a brief characterization of these subjectivities is necessary. The power of environmental and social justice values that have evolved to include the health concerns of members has meant a break from simple material affluence, trust in command-based economies, and their inefficiencies and inflexibility to create values. New social relations and the changing subjectivities are becoming less distinct from notions of organic entities and more self-governing from economic and cultural mechanic determinisms. These relations are more responsive to actual national, regional, and international markets, because actors' affect are part of the intersect movement of food between producers, consumers, and new spaces by which commodity circulation circuits (markets) are formed and valorized. In key areas of market development, greater attention is given to variant processes taken place in the social and private sector, market forces, agriculture, and agriculture's alternative forms of production and consumption, which are in tune with people's corporeal capacities to resituate actions, such as eating, cooking, and enjoyment within the material sphere of nature, new nationalisms, and socioeconomic divisions of the broader economy (Fisher, 2012). Somewhat paradoxically, but not unexpectedly, these material and non-material dimensions of global development, markets and how we live the impact of commodities on our stress and well-being have emerged as critically important in an era of neoliberalism institutional discourse, where increasingly it has become socially visible that the advancement of markets and the agency of producers and consumers depend significantly upon certain values and affects of global development as freedom, well-being, and multidimensional commitments to material and nonmaterial developments of actors' quality of live.

Thus, we are concerned with actors' agency, mobility, and their social actions, as part of the process by which commodity and other social values enter the relationship on actors and their notions of well-being, shaping their practices. This can lead to an extension of the partial connections approach (Strathern, 1991) to focus on the blending and juxtaposition of elements of modernity and tradition in the creation of various modernities, whereby people, ideas, and representations of space are interconnected, but never totally symmetrical or fully

integrated. The field of global development, markets, and well-being offers an especially interesting area of inquiry because it inherently throws up a complex mixture of material and nonmaterial notions of quality of life and explanations of causes of health issues and their implications for an appropriate understanding of the consequences of specific modern global pathways and actor's civic participation.

There is in this characterization a certain mode of fragmented dynamism of experts' global development interventions (i.e., the millennium program of development) and a better appreciation of the ways in which global properties, market relations, and well-being values are generated, and challenged, through the ambivalence and ambiguity for differences practices, interests, and knowledge that are appropriated by local people, delimited, and reorganized by active self-organization, provisional building arrangements, and knowledge interactions that are not local or global, internal or external. The appropriation and incorporation of these exteriorities to the lifeworld of actors allow for the resolution of the practicalities of life (Parkin, 1995). From the actor's standpoint, people's self-organizing practices can only effectively be grasped if we give close attention to actors' identity-recursiveness processes and their representations, images, and normative schemata of what constitutes their quality of life. In this vein a concern for people's well-being is part of a generation of imagined worlds and new situated development forms and practices and not simply the reproduction of existing global arrangement regimes.

To be a member of an imagined – well-being – world is of course to belong to a world populated by material and nonmaterial resources, in the sense that there is no actor that have an immutable and static identity not a single and overarching network that exactly match the qualities or profiles of those who are conceived as the guardians of the existing differences that made visions of the accepted order. If this representation is just partially context defining, then this implies that the examination of global development, markets, and well-being invoke the notion of multiple representations and arrangements. The social space itself is capable of being iterated by violent fluctuations in produce market prices. This has exacerbated a trend among farmers to switch crops following commercial and technological advice, inhibiting local experimentation and innovation (Sillitoe, 2007). This has also contributed to create the occurrence of social unrest among producers and consumers. This social unrest is a distinctive collective process, operating in ways and leading to the generation of 'other' mutual coordination practices, between consumers and producers. In this vein, the notion of well-being is a concept that recognizes the existence of poverty, but it does not recognize it determinacy on peoples' agency and social inactivity.

The Positioning of International Agencies and Knowledge in the New Global Environment

The connection of terms: global development, markets, and well-being have been heavily influenced by the successive rethinking of policy options from within international development agencies (DFID and World Bank 2003, UNDIP report on human resources 1990, World Bank 1989). Hence, its meaning has shifted in accordance with the different policy orientations of the global experts and bureaucrats involved. Dissolving the boundaries between 'externalities' and the social forms that represent responses to policies and programs. This process has tended to promote market models and the Western neoliberal optic of consumerism. This blueprint becomes significant because it entails a technique of representing, organizing and describe the global development affording concepts and policies generated by decision makers themselves. This, once again, challenges researchers to develop further theoretical understanding of agency, material and nonmaterial dimensions of life. Ultimately is important to shift the orientation that demonstrates the effectiveness of state institutions, science, and technology, but also that any scientific knowledge requires an endorsement from peoples' grounded worlds in order to legitimize researchers' observations and new information in explaining health conceptions and practices as part of the notion of peoples' well-being.

Finally, global development, markets, and well-being are ambiguous, political, and pragmatic categories that facilitate rethinking social and policy changes and serves to make us aware of the potential difficulties and different interpretations that 'good governance' and the policy of the development intervention need to address. In the last three decades development studies have shown that aid processes are far more complicated and disrupted in terms of actions and emergent properties evolving between actors and policy makers in charge of distributing aid objectives (Lewis and Mosse, 2000). Chambers (2005) has stressed that perhaps one of the central issues in these policy disruptions is the incompatibility of values between interventions expanding 'global modernities' into multiple localities and the subsequent resistance, struggle, and many unintended consequences emerging, when local people encounter these development policies and representation of Westernized lifestyles.

Indeed, global development, markets, and well-being are part of a research-oriented policy vocabulary attempting to shift the debate from the discourse of neoliberal policy to actors' interpretations of its contents, consequences, and actual social practice. Such shifts underline the need to explore how global development, market values are reproduced, transformed, or subsumed by other values. We need to analyze how these categories intersect reordering peoples' everyday life. This is to forge a new path of policy research, which accords due importance to the appropriation and resituation of multiple forms of value and materialization. In other words, we need to explore the ways in which global development properties are embedded into 'real markets' and quality of life values and social action. This challenge beliefs in the universality and uniformity of the global development that unfolds into the world unproblematically, whatever their market and social value context, offering instead an analysis of the associations and linkages of situated well-being values and markets, against the dominant thinking that opposes citizenry and consumption, neglecting or denying the responsible practices that value-oriented consumers' (i.e., fair-trade) already play in the enactment of learning to be satisfied as global 'reflexive' shoppers.

Conclusion

This article has underlined that the main focus of the relation among global developments, markets, and well-being lies at the very core of grappling with an understanding of contemporary change. Global properties, market beliefs, and well-being values constitute the conceptual field upon which counterworks, countertendencies, and counterpoints to neoliberal ideology and discourse are founded and remain one of the main issues of anthropology of development.

This type of research orientation should be considered a borderland across theoretical representations and ethnographic particularities of self-organizing processes to explain interests and values for the analysis of multidimensional social processes resulting from the incorporation of groups and individuals to develop a far-reaching understanding on what drives well-being of people and nations, and what needs to be done to achieve greater democracy, rights, and development. This orientation may contribute to the democratization of world research. This idea that anthropology of development can generate a global and critical collaborative rethinking may not resolve the differences of power that characterized the world of global development experts, but it might contribute to make less linear and more complex the problems of globalization from below. This means recognizing how people bridge with their practices and actions existing taken for granted differences of the material, immaterial, and hierarchical world of knowledge.

Global Governance

Kennette Benedict, Bulletin of the Atomic Scientists, Chicago, IL, USA

Abstract

Global governance is the purposeful order that emerges from institutions, processes, norms, formal agreements, and informal mechanisms that regulate action for the common good. Global governance encompasses activities that transcend national boundaries at the international, transnational, and regional levels and is based on rights and rules that are enforced through a combination of economic and moral incentives. Mechanisms of global governance are composed of elements and methods from both the public and private sectors. These elements include agreed upon standards, evolving norms based on shared values, and directives issued by private authorities and ultimately enforced by states. Methods of global governance include harmonization of laws among states, international regimes, global policy issue networks, and hybrid institutions that combine functions of state agencies and private sector organizations.

The exercise of global governance raises three sets of issues. The first has to with the legitimate exercise of authority, the second with democratic values, and the third with effectiveness. In contrast to governance at local and national levels, a social contract between citizens and institutions of global governance has not developed to constitute a sufficient basis for legitimate action in all domains. In its current formulations, global governance implies democratic governance by emphasizing openness, accountability, and fairness. However, the reliance on scientific and professional bodies to set standards, on bureaucratic agencies of the state to implement policies, and on voluntary organizations to monitor compliance, none of which are based on democratic principles of representation or equal participation, raises questions about the compatibility of democratic values with the practice of global governance. The effectiveness of global governance is challenged by the worldwide scope of problems, such as climate change, and by the large number of public institutions, private firms, and civil society groups that require coordination to address global problems.

Definition

Global governance is the combination of intentional and patterned human interactions that regulate action worldwide for the common good. It is a purposeful order that emerges from institutions, processes, norms, formal agreements, and informal mechanisms that provide a field of action for human activities. Governance is based on shared expectations, as well as on intentionally designed institutions and mechanisms (Rosenau and Czempiel, 1992; Biersteker, 2009).

In nation-states, the authority of public institutions lies ultimately in the government's capacity to provide societal order and socialize individuals to a common identity, as well as its monopoly of the legitimate use of force (March and Olsen, 1998). In the global context, no world governmental body is responsible for order and stability, nationalism stirs rivalries, and no one institution enjoys a monopoly of the legitimate use of force; no single global authority exists. Yet commerce among countries and firms expands, information is communicated across national boundaries in an orderly fashion, and expectations about rule implementation are shared through transnational networks of private and public agents. Cooperative action is based on rights and rules that are enforced through a combination of financial, material, and moral incentives as well as through the use or threat of force. How this happens is the domain of global governance.

Global governance is distinguished from international relations, which refers to relations among states and to the formal institutions in which states participate, such as the United Nations, the North Atlantic Treaty Organization, or the Association of South East Asian Nations. Global governance includes these formal organizations, but also encompasses activity at the international, transnational, and regional levels that is both within and outside the purview of states. For some analysts, the term includes recognition of the effects of local activity on the global, such as emissions of carbon dioxide on the atmosphere, and global effects on the local, such as transnational capital flows on the health of subnational economies. For most analysts, global refers to those activities in the public and private sectors that transcend nation-state boundaries.

Governance in the Context of Rapid Globalization

Heightened attention to global governance at the turn of the twenty-first century is the result of an increasing understanding of the interconnectedness of human activity on the planet and growing recognition that problems arising from global trade and finance, and from changes in the climate due to human activity, for example, need more cooperation than is possible through states acting together in existing international organizations, such as the United Nations or the International Monetary Fund. The growing interdependence of societies brought about by increased trade and capital flowing across national boundaries, a recognition of the effects of human activity on the biosphere, extensive population migration, and increasing communication between people in far-flung locations contribute to the globalization of human society. Regulating these transborder activities to prevent harm to economic livelihoods, to human health and dignity, and to the Earth's

atmosphere prompt increased attention to the need for improved global governance.

Informal Networks, Formal Institutions, and Incentives

Ordered and patterned interactions on a global scale then are the result of international agreements, of harmonization of laws among countries, of common interpretations of international law, of transnational cooperation among functional agencies, of self-enforcing contracts between private firms, and of standard operating procedures of governmental and nongovernmental organizations. Taken altogether, this array of formal legal arrangements, informal codes of conduct, incentives, and habitual practices based on shared expectations about legitimate action constitutes global governance.

So, for example, the United Nations is a formal international arrangement based on legal agreements among states and is considered to be part of global governance. It is one of many formal institutions, however. Others include the World Trade Organization, the North Atlantic Treaty Organization, the Organization of American States, as well as other regionally based treaty organizations, such as the Association of Southeast Asian Nations, the Organization of African States, and Asia–Pacific Economic Cooperation.

In addition, transnational cooperative actions among national law enforcement agencies, for example, also are part of global governance. Interpol combats illegal criminal activity, like drug and human trafficking, through police agencies that volunteer to cooperate and share information. In civil law, courts set precedents and decide cases based on case law from other national judicial systems. And in commercial law, private mediation is used by business firms, rather than government authorities, to settle disputes (Slaughter, 1997). Finally, over the past two decades, newly created international courts with compulsory jurisdiction are independently applying the rule of law as newly empowered nonstate litigants seek remedies, and courts call upon legal and political networks to pressure states to uphold court interpretations (Alter, 2014).

These informal arrangements are supported by networks of individuals, nongovernmental organizations (NGOs), and state agencies. Cross-government professional relationships provide opportunities to learn from the experience of judges, central bank governors (the Basle Committee), securities regulators (International Organization of Securities Commissioners), and regulators of insurance industries (International Association of Insurance Supervisors) from other countries. These organizations use Memoranda of Understanding to improve the harmonization of regulation on the international level as financial transactions have become increasingly global. Providing for orderly global financial transactions through transnational networks of domestic officials and industry representatives can be quicker and more flexible than negotiating through formal international institutions; new rules can be incorporated directly into domestic law, rather than requiring treaty action.

The development of networks has accelerated with the introduction of high-speed electronic communications technology. Even before these advances, however, travel and telephone communication contributed to a worldwide human rights movement, a global environmental movement, an international women's movement, transnational corporations, and international professional societies. Such networks have established common standards in a number of fields. In the case of human rights, for example, the diffusion of norms about the rights of prisoners and citizens came about through the use of international media to publicize cases of abuse. Similar tactics have exposed poor labor conditions of major transnational corporations such as Nike and Apple. Such public 'shaming' of governments and businesses is based on shared norms about the need to protect individual rights. Some of these values have been codified in formal national and international laws, while others are observed because they enhance the public reputations of businesses and legitimacy of governments.

At its core, the concept of global governance builds on behavioral understandings of law and society, where law is a dynamic and changing reflection of shared standards and values. This suggests that norms of appropriate behavior emerge from daily interactions to solve transborder problems and from a developing consensus about what is fair. These norms may subsequently be codified in law. Compliance is undertaken voluntarily rather than through the use of physical force, although the threat of sanctions, whether criminal or civil, is recognized as an underlying motivator of compliant action. The evolution of GATT into the World Trade Organization exemplifies the formal codification of rules, about international trade in this case, emerging from a process of informal negotiation and standard setting (Abbott and Snidal, 2000).

Both the threat of sanctions and an interest in avoiding harm to themselves are at work. In the private adjudication of transnational business disputes, for example, firms wish to preserve flexibility and avoid undue government interference, which they may view as harmful, so they comply with the judgment of a private mediator rather than taking the issue to a public institution for settlement. Transnational corporations, such as Nike and Apple, will implement higher labor standards if they believe their product sales will suffer if poor worker conditions are brought to light.

Elements of Global Governance

Several fundamental elements constitute the building blocks of contemporary global governance. The most prominent of these are standards, norms, states, and international organizations.

Standards

Agreeing upon and setting standards is one means of coordinating private actions. For example, the standardization of time through the use of Greenwich Mean Time permits coordination of communications, airline schedules, television broadcasting, business deals, and a myriad of daily transactions that we now take for granted. Rules of international navigation and airline procedures ensure the safety of air travel across national borders. A standard railroad gauge eases transborder crossings. Product standardization rationalizes the multinational

manufacturing of automobiles, televisions, refrigerators, and other appliances through ISO 9000. The Society for Worldwide Interbank Financial Telecommunications (SWIFT) ensures that financial wire transactions between banks in different countries are protected from corrupt or criminal practices.

In general, standards are accepted because they are voluntary and are arrived at through the exercise of professional expertise, in which peers or equal actors reach decisions through rational deliberations that are open to interested parties. In practice, the process of standard setting by bodies such as ISO 9000, for example, is completed by those with expertise in fields like accounting and engineering or the Internet, representing users and pledged to serve the public interest. The legitimacy of standards rests upon efficiency and on the desirable consequences of the rule, which allows no exceptions or variations. To the extent that efficiency is a value in itself, and to the extent that professions embody and transmit a set of values, standard setting is not entirely value-neutral. In comparison with hierarchy, markets, or norm-based communities, standardization is a minimal form of governance.

Norms

Norms are internalized rules based on commonly held values. In the international security area, nonuse of nuclear weapons is cited as such a norm. The norm is based in part on a shared revulsion at the devastation to human life and society that is inflicted indiscriminately in nuclear explosions. In the human rights domain, human rights abuses violate widely shared understandings of the inherent value of human life and the appropriate treatment of individuals by their governments.

Shared norms are developed and transmitted through informal networks of professionals and representatives from international institutions, national governments, nongovernmental voluntary associations, and private business (Finnemore and Sikkink, 1998). For example, the International Red Cross advocated for the humane treatment of wartime combatants that resulted in the Geneva Convention by convincing military leaders that protecting the wounded was compatible with their war aims. These commonly held values in many domains, in turn, contribute to the regulation of international conflict, the management of nuclear weapons, environmental pollution, human rights abuses, and humanitarian relief, among others. Some analysts view these networks as an essential component of global governance, providing a way of governing without government (Reinicke, 1998).

States

The organization of nation-states in the twentieth century has depended upon the development of bureaucracy, or hierarchy, as a means of governing. The growth of the modern state has included regulation of markets, of educational institutions, of environmental conditions, of criminal activity – in fact of nearly every aspect of daily life – as a means of coordinating action for the common good. While some of this regulation has come through standard setting and norms development, the characteristic mode of hierarchical government is through directives. These directives are enforced through the use and threat of punitive sanctions, including imprisonment and fines.

The enforcement power of the state is based on its monopoly over the legitimate use of force. This monopoly, in turn, is based on a social contract, whereby citizens voluntarily cede some of their sovereign rights to the government, in return for protection from hostile forces and for a social order maintained by the state. The central problem for theorists and practitioners of global governance is that there is no global social contract and no world government, and yet, transborder activities generate needs for coordination, as well as problems of collective action to deal with externalities, such as climate-changing carbon dioxide emissions.

Some observers locate global governance in a global public domain beyond the sphere of states (Ruggie, 2004), where supranational and private actors dominate in emerging structures that are undemocratic and unequal (Deudney, 2007). Others emphasize the continuing role of states in global governance and document how national laws anchor and promote transnational private financial transactions for economic gain at the same time that national laws are shaped by the actions and needs of private transnational firms (Sassen, 2002). Whether the state is part of or is marginal to global governance continues to be debated. Whatever the outcome of the debate, however, it is clear that events like the global financial crisis of 2007, violent attacks by global terrorist movements, and the lack of concerted action to reduce climate-changing gases challenge state sovereignty and the capacity to protect citizens from harmful transborder flows and activities.

International Organizations

International organizations, ranging from the United Nations, the World Trade Organization, the European Union, the North Atlantic Treaty Organization, to the International Court of Justice, have played more active roles since the end of the Cold War in the early 1990s. Their influence is sometimes difficult to evaluate, and their failings are often the subject of negative comment, as when the UN Security Council failed to intervene in genocides in Rwanda and Darfur. Yet the positive contributions to more efficient collective state action, as in state pooling of financial resources for economic development in poor countries through the World Bank and the International Monetary Fund, are often taken for granted (Abbott and Snidal, 1998).

In a particularly telling contrast, UN conferences that have sought to commit member states to reductions in their carbon dioxide emissions that disrupt the Earth's climate have failed over the past 40 years. Yet the UN-supported Intergovernmental Panel on Climate Change, which collects data from scientists worldwide and reports the findings in consensus documents, has been very successful. Indeed, it has presented the public and policy leaders with remarkably clear analyses of large bodies of data and provided a clear scientific basis for government action.

However, industrial countries belong to a plethora of international, regional, and issue-specific organizations that overlap in ways to actually cause conflict and complicate national decision making. The decade-long international dispute over bananas between the European Union and the

United States illustrates the complexities and costs of overlapping jurisdictions, in this case, the nesting of the banana regime within the EU, the Lome Convention, and the World Trade Organization (Alter and Meunier, 2006).

Newly established international courts are emerging as autonomous interpreters of the rule of law as well as arbiters of disputes between states. The rise of compulsory jurisdiction that allows international commissions, prosecutors, and private parties to initiate litigation enables international courts to interpret the meaning of international law independently from state interests. In effect, changes over the past 20 years have removed the monopoly power of national governments and domestic judges to define what international law requires even within their own jurisdictions. Much as states have tasked international financial institutions with aiding poor countries and regulating trade disputes, states have tasked international courts with helping to enforce international law (Alter, 2014). In cases ranging from prosecuting war criminals, to enforcing international conventions against human trafficking, to establishing labor rights, courts have interpreted and enforced new international law. And, whereas states have traditionally enforced laws through coercion and punishment, international courts enforce laws with the aid of transnational organizations, international public media, and legal actors to pressure governments to comply. As domestic courts often effect changes in legal interpretation by expressing a public consensus about the expansion of rights even at the expense of dominant interests, international courts are acting independently from powerful state interests to make findings from the perspective of rule of law.

Methods of Global Governance

Elements of governance – standards, norms, state capacities, and international organizations – are used in combination to coordinate action, solve transnational problems, and manage conflict, and together constitute global governance in practice. Among the most effective methods are harmonization of laws, international regimes, global issue networks, and hybrid public–private institutions.

Harmonization of Laws

The implementation of formal international agreements is accomplished through the adoption of national laws to bring local and national practices into compliance with international rules. For example, carrying out the provisions of the Montreal Protocol to protect the atmospheric ozone layer is accomplished through legislative action in each country to bring manufacturing practices into conformity with the Protocol's agreed directives to reduce production and release of chlorofluorocarbons.

Legislative action is one path to harmonization of laws. Another is through the courts and judicial systems of countries. A body of transnational law is developing informally in which judges in one country are basing their decisions on precedents and case law from other countries (Busch and Jorgens, 2005; Slaughter, 1997). This is taking place in areas of civil and commercial law, through observation and borrowing, where standard rules help to smooth business and legal transactions in what is conceived as global public administrative law (Kingsbury et al., 2005). In the area of human rights law, courts are citing cases in other national jurisdictions, in addition to the United Nation's Universal Declaration of Human Rights, as precedent and to lend credibility to decisions about the protection of civil and political rights in their own countries.

International Regimes

International regimes are defined as a "set of implicit or explicit principles, norms, rules, and decision-making procedures around which actors' expectations converge" (Krasner, 1983). The effectiveness of a regime rests on the operations of institutions, organizations, governments, and international bodies that share a set of principles, rules, and norms in a particular area of international action. Although regimes include formal treaties and national law, they also rely on informal norms and networks to develop and enforce standard behavior in an area of global policy.

For example, regimes to control the development and spread of nuclear weapons had been relatively successful in the context of the Cold War. They were critical to controlling the US–Soviet arms race, to preventing nuclear war, and to limiting the spread of nuclear weapons technology and weapons. These regimes had their basis in a number of formal treaties and international agreements, such as the Anti-ballistic Missile Treaty of 1972 and the Nuclear Non-proliferation Treaty of 1968, as well as selected enforcement powers through the United Nation's International Atomic Energy Agency. They were shaped as well by the informal meetings, discussions, networks, and personal relationships of scientists and other experts working across national boundaries to formulate these agreements (Evangelista, 2002). To ensure compliance, regimes relied on formal and informal surveillance techniques and the trust that emerged from shared norms about the dangers of nuclear weapons, their development, production, and proliferation (de Nevers, 1999).

The World Trade Organization (WTO), along with the OECD's system for accepting data on product testing, multilateral agreements on investment, and other regulations, constitute a regime that provides order in trading between and among countries. The regime provides for standards, regulates tariffs, and adjudicates disputes among countries to prevent trade wars. Although still regarded as an institution that favors developed countries, WTO inclusion of environmental standards and labor provisions has enhanced its legitimacy as a global organization that can effectively resolve disputes, especially between emerging economies and established industrial countries.

Global Policy Issue Networks

Development of global policy and implementation of common laws also depends on informal networks of organizations and individuals. These networks are composed of individuals who share an interest in providing a public good that may not be provided by any single nation-state. Through communication networks, sometimes built around professional associations and scientific bodies, these transnational

action networks (Keck and Sikkink, 1998) or epistemic communities (Haas et al., 1993) provide information, documentation, and alternative policy solutions to global policy problems.

Some of the most visible networks have formed since the mid-1970s on human rights, environmental protection, communications technology, and women's issues. In each of these areas, lawyers, scientists, and political and cultural leaders have found counterparts in other countries to form worldwide movements that have publicized the harm brought about by current national policies and practices. In the case of women's issues, the actions of nongovernmental organizations at United Nations conferences on women and on population were essential to changing norms and practice. At the 1995 population conference in Cairo, the recognition of women's empowerment as a key path to fertility reduction, rather than an emphasis on birth control, demonstrated the influence and effectiveness of women's issue networks in shaping global policy. The adoption by the United Nations of the concept of the 'responsibility to protect' emerged from policy networks, high-level commissions funded by private foundations and governments, and in response to the shameful genocides in Rwanda and Bosnia in the 1990s that violated shared norms about the protection of civilians in conflicts.

Hybrid Institutions

As transnational activity has increased, as nongovernmental actors have become more prominent, and as national governments have devolved authority to private sector bodies, new institutional arrangements have developed to manage global relations. These arrangements are referred to as hybrid institutions or public–private partnerships because they mix private sector organizations and a variety of incentive systems with governmental agencies to achieve public goods. They combine standard rules, private market arrangements, nongovernmental norm-based organizations, and government agencies – both national and international.

Some of the most inventive have emerged in the area of environmental protection. The certification of sustainably harvested coffee or forest products is an example of hybrid global governance institutions. Presented as an alternative to governmental regulation of the timber industry, environmental nongovernmental organizations have convinced major private firms in the forest products industry that consumers will pay premium prices for furniture and other lumber products that are sustainably harvested. To ensure compliance, private firms participate in a council of producers, scientists, and other independent interests that inspects production operations and certifies that manufactured products are derived from sustainably harvested lumber. The manufacturer uses that certification to appeal to consumers who are willing to pay higher prices to protect natural resources. The process takes place without government intervention, includes market incentives, and relies on professional expertise and standardization to enforce rules. Similar certification institutes have been established for textile manufacturing and diamond mining.

The prosecution of transnational criminal activity involves another kind of hybrid institution. Organized crime has become relatively border free, especially as liberalization of economic relations has taken place, yet law enforcement jurisdiction remains within fixed territorial legal frameworks. To deal with this challenge, law enforcement agencies have developed cooperative relationships with their counterparts in other countries, as well as with banking institutions, to share information and to apprehend criminals. Interpol, a voluntary association of police departments from around the world, has made 31 000 arrests in the past decade to bring malefactors in the illegal transnational drug trade, the arms trade, human trafficking, and other criminal activity, to justice (Barnett and Duvall, 2005).

Issues in Global Governance

While new modes of coordinating transborder activity are emerging that hold the promise of effective global governance, theoretical and normative challenges have been raised. Three are addressed here: effectiveness, the legitimacy of global governance bodies, and the democratic nature of these global governance processes.

Effectiveness

The problems that global governance is intended to address are beyond the scope of any one national government to solve. Yet, without the usual tools of government, including legitimate use of force to induce compliance, governance at the global level often fails. Enforcement of the Nuclear Nonproliferation Treaty is compromised by lack of automatic sanctions for countries such as North Korea, Libya, and Iran, when they withdraw from the treaty or engage in bomb-making activity, or for European suppliers that provide equipment to the illicit nuclear weapon network of Pakistan's nuclear scientist A.Q. Khan.

When the interests of a coalition of states can be met through international organizations, as in the case of removing chemical weapons from Syria in 2014 by the Organization for the Prohibition of Chemical Weapons, global agencies can provide expertise and coordination of state parties to international conventions. But more often, global governance is frustrated by lack of agreement about how goals should be met, as in the failure to agree on goals and quotas for reducing carbon emissions that are warming the Earth's atmosphere, or in devising common rules for regulating securities and financial transactions worldwide with the result that the global economy suffers in 2014 from volatility that dampens recovery from the world recession of 2008. In another example, prompt coordination to prevent the spread of deadly pandemics is hampered by lack of state cooperation in reporting outbreaks. Officials may fear a halt in international tourism and loss of trade if they do report emerging epidemics, but they also may suffer from a lack of faith in the effectiveness of global institutions like the World Health Organization. This lack of information sharing, in turn, further reduces the effectiveness of global governance.

One way to increase the effectiveness of global governance is to instill heightened belief in the legitimate action and authority of global institutions. This is the next challenge to be addressed.

Legitimacy and Authority

Successful governance requires the consent and compliance of those whose activity is being governed. In other words, to be effective, practices and institutions that constrain actions must be accepted as legitimate. This aspect of contemporary global governance remains problematic. In theories of the state, social contracts between citizen and government have depended on citizens relinquishing some rights in exchange for physical protection. But no such social contract exists at the global level (Barnett and Duvall, 2005). At the most, legitimacy claims have been based on what works well, what is efficient, or what is reasonable in the eyes of those seeking solutions to transborder coordination and public goods problems (Deudney, 2007).

Issues of legitimacy become even more vexed with the increased participation of nongovernmental organizations in issue networks and hybrid institutions. While the authority of governments and the legitimacy of private firms are based, in some measure, on implicit contracts with citizens or consumers, respectively, the authority and legitimacy of nongovernmental organizations is based on their claims of acting in the public good – as they define it. Whether protecting individuals by calling attention to the human rights abuses of their own governments, or conserving biodiversity in the face of extractive private industry, or saving women from customary rituals that cause physical harm, nongovernmental actors believe they are upholding standards that are in the interests of all humanity.

These organizations, however, are not assembled through an election process or any other democratic procedure. They are self-appointed and claim to be acting on the basis of values that serve a global public interest. Without an authoritative institution that provides a process for establishing common values and agreement on what constitutes the public good, issues of authority and legitimacy in global governance will most likely remain unresolved.

Democratic Values and Fairness

While some definitions of global governance emphasize the neutral management of human affairs, there is a strong normative component to the term that leaves underlying assumptions about who governs and with whose standards largely unexamined (Barnett and Finnemore, 2004). The strongest challenges to current practices of global governance come from developing country analysts who observe that emerging global standards and norms are based on industrial countries' interests and values (Hurrell, 2007). They suggest that the dominance of power politics in international institutions, the disparity of wealth between North and South, the intolerance for differences in values, the resort to force to resolve international conflicts, and the neglect of environmental degradation are major deficiencies of global governance.

To reform current practices, critics encourage equal participation by developing countries in international institutions and suggest treating dominant powers like the United States as normal countries that must abide by international law. Chinese analysts, in particular, would strive for a harmonious world of justice and common prosperity. They observe that globalization has disproportionately benefited developed countries and contributed to inequality everywhere which is undemocratic and which undermines peace and stability. And global governance mechanisms to manage globalization have grown out of and are imposed by Western ideology and values on the rest of the world. To rectify these disparities, global governance should encourage technology transfer, provide more aid to poorer countries, and in general, promote shared development and common prosperity. Furthermore, recognizing the diversity of civilizations and tolerance for alternative methods of problem solving would provide a richer set of ideas for managing transnational issues and would enhance the legitimacy of global governing mechanisms (Wang and Rosenau, 2009).

While the challenges to current conceptions of global governance may be growing, practices continue to evolve along with calls for transparency, accountability, and protection of individual rights (Ruggie, 2004). The informality and pluralism of global governance both recognizes and requires the contributions of private firms, nongovernmental actors, and informal networks in policymaking. Yet the reliance on unrepresentative scientific and professional bodies to set standards, on bureaucratic national and international agencies to implement policies, and on unelected voluntary organizations to monitor compliance raises questions about the compatibility of democratic values and the practice of global governance.

The increasingly acute challenges to human welfare from rising inequality within and between countries, and from the stresses on societies from climate change will propel transborder activity, on the one hand, and, on the other hand, may induce fear and a retreat to state-centered isolation. The web of networks, institutions, rules, and norms that constitute global governance has thickened dramatically over the past 30 years to meet some of the challenges of economic globalization, promote the spread of universal human rights, and conserve biodiversity of species in the world, among others. Whether the effectiveness, legitimacy, and the authority required to resolve the global crises of the environmental commons, of growing inequality, and of increasing instability and violence will emerge quickly enough to prevent cataclysmic suffering remains to be seen.

Abstract

Global (universal, world) history includes attempts to construct histories concerned with the evolution of humankind that are intellectually inclusive (no discipline or approach to the subject is ruled out); unbounded by geographies, let-alone national frontiers and resolutely unfettered by established chronologies for the construction of European, American, African, Asian, or other national histories. This article elaborates upon the long historiographical tradition of the writing of global history, explains why a renaissance of that tradition is now clearly underway, deals with mainstream and postmodern objectives to the field, and elaborates upon two distinct approaches that exemplify and categorize the increasing flow of modern publications labeled as global history.

Global (universal, world) history includes attempts to construct histories concerned with the evolution of humankind that are intellectually inclusive (no discipline or approach to the subject is ruled out); unbounded by geographies, let-alone national frontiers and resolutely unfettered by established chronologies for the construction of European, American, African, Asian, or other national histories. This article elaborates upon the long historiographical tradition of the writing of global history, explains why a renaissance of that tradition is now clearly underway, deals with mainstream and postmodern objectives to the field, and elaborates upon two distinct approaches that exemplify and categorize the increasing flow of modern publications labeled as global history.

Historiographical Traditions

Global histories have been written since Herodotus (495–425 BCE), whose cosmopolitan concerns were commended by Cicero but deplored by Thucydides – who opined that Greeks had no business investigating alien mythologies, religions, customs, and traditions. History writing, Thucydides suggested, should be modeled upon his own study of the Peloponnesian Wars – sharper in focus, shorter in time horizons, based upon verified facts, and prescriptive in purpose. Fortunately, Herodotus ignored his 'Eurocentric' advice and ranged widely beyond the Hellenic world to include Egypt, India, Babylonia, Arabia, and Persia in his histories in order 'to preserve the memory of the past by placing on record the astonishing achievements both of our own and of the Asiatic peoples.' He used oral testimony, archeological remains as well as written sources and imposed some chronology and order on streams of events that had occurred on several continents and over long spans of time. His (still popular) book ends in 'European triumphalism.' Its story turns into celebration of the victories of the Greek *polis* (especially Athens) over the Persian Empire, which Herodotus represented as a conflict between occident and orient, despotism and freedom.

Global historians applaud Herodotus for his reflexive interest in barbarian virtues and regret the long hiatus that occurred in the writing of secular world histories until Voltaire and his generation carried the project forward again during those brief decades of Enlightenment, before the outbreak of the French Revolution. They are puzzled, however, to observe that with the exception of a few Stoics (Diodorus, Polybius, and Dionysius) and a handful of geographers and ethnographers (Strabo, Ptolemy, and Pliny), histories of the world did not attract more scholars writing during Graeco-Roman times. Although they lived in empires that maintained contact with an array of cultures (African, Arabian, Persian, Indian, and Chinese), historians of the classical era remained overwhelmingly concerned with Europe. Their histories (e.g., Tacitus) deal mainly with the politics and scandals of Rome, or (e.g., Thucydides) with wars among Greeks. Their equally provincial oriental contemporaries, residing in that celestial empire on the other side of the world, asserted with quintessentially Chinese superiority that they remained unimpressed with anything the Romans had to impart, or to trade for, China's silks, ceramics, medicines, perfumes, and spices.

In Europe, steps in an ecumenical direction occurred when Christian and Jewish historians started their narratives with the Creation and set out to ensure that Greeks and Romans should not be left (in the words of Josephus) 'as the arrogant possessors of antiquity.' That was why Orosius (a student of St. Augustine) proclaimed that "The Roman Empire arose in the west but was nourished in the east." Narratives in Christian historiography are dominated by chronicles about the evolution of mankind over stages of history, no longer bounded by the frontiers or cultures of the Greco-Roman world. In 1158, Bishop Otto of Freising recognized that "all human power and learning had its origins in the East." Medieval historians included Oriental and African civilizations right down to the Reformation when Catholic and Protestant intellectuals began to look for a usable past to help princes to integrate populations and secure the frontiers required for the formation of nation states. Even then both parties to Europe's conflict over religion and national identities remained aware of places, peoples, and cultures not merely outside the borders of their enclosed and ideologically encompassing polities, but beyond Christendom itself, and that is hardly surprising.

Residing on an underdeveloped promontory on the western edge of the great Eurasian landmass, with ice to the north,

uncharted oceans and territory to the west, and the hostile power of Islamic communities to the south and east, Europeans had not secured their frontiers, religions, cultures, and technological superiority over other civilizations, long before the eighteenth century. It took centuries to clear the Iberian peninsular of Arab power. Moslem fleets threatened European shipping in the Mediterranean for another two centuries after the surrender of Grenada. Turkish armies crossed into the Balkans in 1350, took Constantinople in 1453, and menaced Vienna as late as 1683. For nearly 1000 years after the fall of Rome, Christendom braced its defenses, imported useful knowledge, shaped its collective identity, and composed ideologically charged histories in the context of conflicts (and encounters) with the powerful civilization of Islam on all its frontiers. Memoirs, travelogs, diplomatic correspondence, and investigations into Arabic medicine and astronomy, together with commercial intelligence on societies under Ottoman dominion, flowed from east to west. Much of this knowledge came through Genoa, Florence, and Venice, along with spices, herbs, sugar, botanical drugs, jewels, chinaware, silks, cottons, and metal goods, imported through the Middle East, from India and China. The expense of procuring and transporting luxuries moving slowly, over long distances and subject to extortionate charges for protection along the way, prompted Europeans to seek ways to surmount the barriers to commerce with South Asia and the Far East by their Islamic enemies.

Shortly after the voyages of discovery, Europeans broke out of their political, commercial, and mental encirclement by Islam. Over the sixteenth century, flows of information into Europe widened to include the Americas, and increased exponentially as a result of the establishment of regular and direct trade and contacts by sea with India, China, South-East Asia, and Africa. Yet nearly two and a half centuries elapsed before Europeans produced a secular and enlightened school of world historians. Its godfather was Voltaire, who composed a history concerned with "only that which is worth knowing; the spirit, the customs, the practices of the principal nations based on facts which one cannot ignore." Voltaire and his followers in France, the Netherlands, Scotland, Naples, Germany, and other parts of Europe deliberately constructed histories of their expanding world in ways which they conceived as a departure from the providential narratives of their clerical predecessors and the 'nationalism' of historians writing for princes and their obedient subjects. That aspiration was propitious. As a result of regular contacts and commerce, the trickle of information about peoples, geographies, technologies, politics, warfare, customs, manners, and the import of all sorts of commodities and artifacts turned into a river of knowledge about places, populations, societies, and economies beyond Europe. For radical intellectuals, China became an alternative model, favorably contrasted with Europe's political systems, social arrangements, and religious beliefs. European histories became not only wider but also deeper as scholarship took over from propaganda, sycophancy, fantasy, religion, and national ideologies.

For something like half a century before the French Revolution and the takeover of India and South-East Asia, European historians resituated Europe's and Christendom's place in world history by including more ancient as well as classical Mediterranean civilizations and by widening their gaze to take China, India, and Japan as well as the newly discovered Americas into account. Europe's new school of world historians dealt with the natural histories, religions, and ethnographies of most parts of an increasingly interrelated universe. Favorable interpretations of oriental polities, societies, cultures, and religions by philosophers and physiocrats did not go unchallenged. Bernier and Leibniz, Montesquieu, Defoe, Winckelman, and Hume remained resolutely unimpressed with the Chinese empire. Nevertheless historians of that era engaged in debates about cultures, geographies, and spans of time that their modern counterparts (confronted with libraries of knowledge and professional interpretations) can only envy.

Alas, the ironic reflexion that their narratives of Enlightenment brought to the task of repositioning Europe in a secular history of the world was overshadowed by a tradition of Western triumphalism which emerged in the aftermath of the Revolutionary and Napoleonic Wars, 1789–1815 when Europeans acquired massive additions to the populations, territories, and natural resources of other continents under direct or informal control. During an 'imperial meridian,' European naval and military superiority over the states and societies of other continents emerged as irresistible. Furthermore, by 1825, European settlers throughout the Americas and the South Pacific had escaped from all metropolitan and aristocratic restraints upon their economic activities and their relations with the indigenous peoples of colonized worlds. White settlers became free to exploit 'their' heritage under rules of their own making, tempered only by religion. As its technological and economic lead over other continents widened, Europe moved clearly onto a path which led, as time went on, to clear divergences in levels of productivity and living standards between East and West and North and South.

Against this background, the writing of history by Europeans departed from its moment of cosmopolitan enlightenment, moved in a Hegelian direction, and returned to the introspection and cultural arrogance associated with imperial Rome. Here and there, aspirations to write universal histories survived. Isolated scholars eschewed the condescensions embodied in the nineteenth century science, technology, liberalism, and colonialism, and a scatter of historians continued to work outside the encompassing national frameworks, and dominant teleologies associated with the rise, rationality, and hegemony of Europe. Nevertheless, it took the destruction and cultural shock of two world wars in the twentieth century to encourage a return to the rewriting of histories of mankind. That program, conducted by a small group of erudite scholars, began in the climate of pessimism and breakdown in the liberal consensus that followed the Great War, when Spengler, Toynbee, Sorokin, Wells, Mumford, and Dawson wrote universal histories of humanity to help Europeans comprehend the decline and barbarity of the West. In history, they attempted to find some substitute for Neitzche's proclaimed demise of Christianity and rationality. Their scholarship is inspiring, but their explicit search for spiritual meanings in the histories of the rather amorphous entities called 'civilizations' did become a compelling framework for scholars and students to work within. The attempt by UNESCO, after the World War II, to fund the writing of a multivolume collaborative history of the world (designed to promote peace across nation states) failed to provide

a paradigm for the reconstruction of secular of histories on an ecumenical scale. Long after the war, historical scholarship continued to be located where its founders had situated it from the time of the Renaissance and Reformation onwards – namely, within the confines, chronologies, and parameters established for comprehending the origins and evolution of European (including North American and Australasian) societies and nation states.

Globalization and the Revival of Global History

Fortunately pockets of global history survived – notably at the universities of Chicago, Northwestern, and Leipzig. Complementary branches of scholarship continued to flourish in the forms of survey courses in Western civilization; area studies, histories of trade and imperialism, investigations into the impact Western technology and culture upon other peoples and above all, as flows of encyclopedias, chronicles, and textbooks for schools and popular education concerned with the world as a whole. Thus, 'tribes' of professional historians with interests in fields that transcended nation states and Europe possessed the credentials and remained ready to refashion their intellectual identities, when demands for global history reappeared from the late 1970s onwards. That revival could be retraced to canonical publications by M. Hodgson, W. McNeill, and L. Stavrianos, but research and teaching has only matured into university programs for the sustained study of world history over the past quarter of a century of 'globalization.' Although there is nothing particularly new about the current phase of economic integration and interdependence, which are the core features covered by that label. Long-distance trade goes back millennia to prehistory, and the exchange of commodities across frontiers and overseas had always involved arrangements for counterpart flows of funds, conversions of currencies, and the operation of transnational, commercial, and financial organizations of a more or less sophisticated kind within and across Europe, Africa, and Asia.

Nevertheless, real discontinuities had occurred. For example, by the late nineteenth century, supported by steam-powered ships and trains, the volume of commodities and services traded across national borders, continental boundaries, and oceans had increased dramatically compared to 1800. Commerce was promoted and sustained by movements of capital, migrations of labor, and transfers of technology and information around the world on an unprecedented scale and at ever-increasing speeds. Political impediments to international flows of exports, imports, money, credit, capital, labor, technology, and information diminished sharply during the liberal international order that prevailed between 1846 and 1914.

State controls revived again during nearly four decades of neomercantilism that succeeded World War I; when governments everywhere sought to insulate their domestic economies from inflows and outflows of commodities, from the emigration of their nation's capital and skilled labor, and from fluctuations associated with unregulated rates of exchange. In the interests of narrowly defined national competitive advantages and political stability, sovereign states proceeded to delink economies from participation in an evolving global economy. Between 1914 and 1948, overall levels of world trade fluctuated in volume, but ceased to grow. Warfare and political regulations depressed movements of capital and labor across frontiers. Controls on the convertibility of currencies hampered international exchanges of every kind.

Normalcy returned after World War II when a discernible shift toward liberalism in the political and legal framework for commerce among nations was also promoted by even more radical improvements in new technologies for the transportation of goods and people across space and time; and by vastly more efficient communications systems for the widespread diffusion of commercial intelligence, messages, and cultural information between distant locations and separated populations. Revolutions in transport, television, and communications widened markets and created opportunities for the organization of transcontinental and multinational business across an expanding range of production, distribution, finance, and commerce.

Unsurprisingly, the implications of 'globalization' for hitherto separated communities, bounded spaces, distinctive cultures, partially connected local economies, and nominally sovereign states have been analyzed by social scientists. Intensified demands have appeared for historians to supply perspective on trends toward integration – that often appear to economists, political scientists, sociologists, and philosophers (as well as natural scientists) to represent profound discontinuities in the ways that ubiquitous technological, economic, and cultural forces are clearly shaping our interconnected world. This demand is supported by Western governments, uneasily aware that their powers to control societies, nominally under their rule, are transforming their claims to effective sovereignty over the populations, territories, and assets within their borders into something more tenuous than used to be the case during the long era of competing nation states. Their anxieties (eloquently fostered by 'official' intellectuals) have been compounded by recent military, technological, and economic achievements of several Asian societies, especially Japan and, the 'Tigers' but latterly (and more significantly) by the reawakening of China. The rest are perceived to be catching up and modern mercantilists (who continue to conceive the world in terms of winners and losers or clashes of civilizations) worry about the relative decline of Western hegemony. Politicians and publics turn to historians for explanations of the past and more reassuring predictions of the future.

National frameworks for political action and academic enquiry are now widely recognized as unsatisfactory. That comprehension is patently functional for natural sciences investigating environmental issues, for biological sciences concerned with the health of human populations, and for social sciences analyzing international relations, crime, migration, communications, and whole ranges of economic activity, which can no longer be regulated within the boundaries of nation states. It is also clear that national and local cultures are being subverted by advertising, by fashion, and by the popular arts, especially music. The means and media of modern transportation, travel, and communications (cheap and available to the masses) are opening up cosmopolitan discourses (usually in English) that contribute to the reshaping of personal identities around the world and transform frameworks for behavior, especially among younger generations.

Traditional, Postmodern, and Global Histories

Pressures to make, write, and teach histories of the world that might become more contemporary and relevant has encouraged the discipline to become less intellectually, politically, spatially, and chronologically confined. They are intensifying, seem irresistible, and are being welcomed as a return to the ecumenical programs of Herodotus, Vico, Voltaire, Leibniz, and von Ranke who opined "there is no history but universal history as it really was."

Intellectual arguments for resituating national and European histories into frameworks that might better address the problems of the new century have been persuasively rehearsed by proselytizers for global history in recent years – as indeed have their antitheses – recommendations to concentrate attention upon microhistories of difference, diversity, and a stance of humility toward the complex histories of 'unknowable others.' That postmodern exhortation is understandably suffused with a concern that the revival of global history will implicitly celebrate 'triumphs of the West' in science, technology, military power, and economic development. Unfortunately that has already occurred in several recent publications by journalists and even by historians whose pretensions to offer overviews of world history seem truncated in time, confined in space, and selective in areas of social endeavor emphasized for recognition as universal achievements; and whose understanding of environmental, biological, and other natural constraints on human action look unscientific.

As humanistic scholarship, global history aims to mature into a renaissance and not a return to the arrogance of Rome or to Victorian triumphalism. Modern history has matured into a capaciously catholic subject, willing to take many kinds of hitherto myopic exclusions into its narratives, to reposition knowledge of the past into more relevant spaces, models, and chronologies, and to plunder the natural and social sciences (as well as archeological remains) for insights into the evolving human condition. In finding voices and viewpoints to construct histories on a global scale, historians (alive to the second cosmopolitan enlightenment that emerged during the closing years of an otherwise dark twentieth century) have not found it difficult to detach their narratives from another politically correct but romanticized appeasement of the underprivileged on one hand, or from the implicit denigration of non-Western people and cultures that flows from Eurocentric convergence and modernization theory on the other.

In an ongoing search for strategies to teach and write compelling histories on a global scale, they will respect the preferences of their colleagues, whose postmodern anxieties about their capacities to comprehend 'others' or to offer plausible conjectures and metanarratives about major trends and significant events, leads them toward dense description, microhistories, and biography. Such flowers should certainly bloom, but the intellectual effort required to landscape the garden also demands attention and imagination from historians.

Global historians confront more challenging intellectual problems in trying to persuade the majority of their academic colleagues (writing bounded histories and bunkered in the security of national archives) that their attempts to write on a global scale could meet the standards of a discipline deeply concerned with detail and documentation that discourages generalization beyond strictly confined geographies and periods. Having rejected Toynbee's quest for spiritual guidance as a tenable mission, global historians tend to make a general case behind arresting metaphors extolling the need for histories constructed as 'maps on the largest scale,' as 'photographs taken through the lenses of wide-angled cameras,' as 'architectural frameworks' and 'as views; contemplated from space.' Many contend that the boundaries and chronologies of parish, let-alone national or continental histories seem equally problematical to define. Nevertheless, coming as most do, as recognized specialists in but one or two fields of history, global historians remain conscious of their credentials and are entirely sensitive to their epistemological vulnerability. It continues to be much easier to conduct research, claim territory, and acquire status as national or local historians.

Current Paradigms: Connections and Comparisons

Nevertheless, historiographical and methodological discussion as well as the volume of publications (off- and online) has increased exponentially. Most of the bibliography is concerned with connections and comparisons across national frontiers and cultural boundaries. Most of it displays a scientifically informed appreciation of evolutionary environmental and biological constraints on all forms of human activity, and represents a welcome reunification of natural and human history. Celebrated and influential books display a talent for the construction of synoptic histories about matters that have been important for humanity as a whole. As more historians risk writing on a grand scale, the field looks set to produce plausible, but competing metanarratives into which the overwhelming flow of parish, regional, and national histories could be reconnected.

Meanwhile two distinct approaches have already been developed. First (and central) is the model, persuasively exemplified and elaborated in several books by McNeill. He has inspired a program of historical investigation into connections across continents, countries, and geographies as well as through very long spans of time. McNeill's assumption is that such connections, interactions, encounters, and contacts with outsiders can be represented as the origins and engine of economic, social, political, military, cultural, religious, technological, and all other conceivable types of change studied by historians; and that connection can be pursued with scholarly detachment and a proper appreciation of the long chronologies required to construct histories that aim to select and analyze major forces at work in the evolution of humanity, McNeill's recommendations aim to avoid the condescension of cultures, the restrictions of time, and the arrogance of nations built into currently dominant styles of history. His (and Crosby's) books show that 'interactions' were often malign: the spread of plagues, diseases, and parasites; those waves of destructive invasions by nomads; wars of conquest, plunder, and imperial expansion; forcible conversions to alien systems of religious belief; and the subversion of indigenous traditions, cultures, societies, and communities by strangers have been part of the universal experience of suffering.

Well-specified types of connection can be investigated over significant periods of contact and transformation. Its taxonomical divisions include trade, investment, warfare, religion, migrations, transfers of useful knowledge, technological diffusion, botanical exchanges, and the spread of diseases. Proper attention is also accorded to the means of transportation and modes of communication that secured, facilitated, and cheapened contacts by sea, land, and latterly by air. Once a relevant range of major connections are traced, understood, and their significance evaluated global history will broaden our education and provide the spatial and chronological perspectives required for the appreciation of the histories of nations, peoples, localities, and groups embodied within particular histories that the majority of their colleagues study in greater depth and sophistication, but too often in isolation.

Put simply, the second major approach extends geographical catchment areas for comparative histories of topics that could be the subject of illuminating study across national boundaries, continents, and separable cultures. Although the linguistic qualifications for such research are extremely difficult to acquire, and the scholarship needed to make sense of contrasts discovered is formidable, the methodological problems are similar to those encountered for exercises conducted within European, national, or indeed regional frameworks.

Comparative history helps scholars to surmount the complexity and tyranny of local detail and seeks to offer coherent but sensitive answers to a great variety of questions that historians select for investigation. For global historians, the illumination derived from the method tends to be realized when they can concentrate upon well-defined artifacts, institutions, organizations, social practices, attitudes, and beliefs that are found in dispersed cultures, and which have already been studied in scholarly depth, in the context of particular locations and which exhibit comparable, but, more importantly, dissimilar geographical economic, political, social, and other features. Then, as Marc Bloch anticipated, the "comparative method can elicit from the chaotic multiplicity of circumstances those contrasts which were generally effective."

In order to communicate salient differences, global historians will be tempted to aggregate and average contrasts across wider spaces and larger populations (continents, oceans, and civilizations) than their colleagues who have the sources to engage in exercises in comparative history within circumscribed boundaries. For purposes of research, designed as building blocks for the production of metanarratives that are truly universal, the comparative method looks set to dominate the field for years to come. It has, for example, already generated a bibliography of global histories concerned with the family, youth, marriage, diet, housing, health, military organization, government, human rights, parliaments, nationalism, religions, fundamentalism, and revolutions, and there are serious debates on two seminal topics: gender and long-run economic growth.

Comparative Histories of Gender and Material Progress

Gender is perhaps the quintessential 'analytical category' for purposes of universal social history and it interacts with other categories including class, ethnicity, race, nation citizenship, and colonialism for purposes of constructing world histories that 'keep humanity in view.' Yet no surprise will be occasioned by the appearance in recent decades of histories seeking to encompass the world economy – going way back in time and written to expound and to explain the disparate levels of material progress achieved by countries, societies, and communities located on all continents. Most people, in most places for most of history, have been preoccupied with obtaining food, shelter, clothing, and other manufactured artifacts that they required to sustain a basic, a comfortable, and, only latterly, an agreeable standard of living.

A modern generation of historians is resituating the scientific, technological, and economic achievements of Western societies in global context. They call upon libraries of books and articles dealing with African and Asian agricultures, industries, towns, commercial networks, communications, trade, science, technologies, cultures, business organization, taxation, state systems, Government policies, etc., covering the last millennium and written in large part by historians from universities not long emancipated from imperial rule. This enormous, but still far from comprehensive, volume of historical research has, moreover, been communicated to the West by specialists in area studies from North American, European, Australian, and Japanese universities. Not long after World War II and during an era of decolonization, historians were offered the opportunity – provided by the accumulation of a large body of archival knowledge – long available in Europe and North America, but emerging in Asia, the Middle East and Africa and Latin America – to reposition their hitherto disconnected histories of wealth and poverty one against another in order to construct global histories of material progress that might have satisfied the aspirations of Montesquieu, Voltaire, Smith, and their 'enlightened' followers, and pleased Max Weber.

Recent attempts to survey this monographic literature have been dominated by scholars from Western universities. Syntheses from China, Japan, India, Africa, and the Near East would be a salutary correction to what is a plural but nevertheless European perspective. Meanwhile, scholars have carried forward a Weberian program for teaching and writing a truly global history of material progress. They have found that the quantitative evidence for such purposes would certainly not be regarded as sufficient to underpin a serious program of historical research designed to account for long-term economic success and retardation among the national economies of Western Europe, North America, and Australasia. In the absence of hard data or even of an acceptable range of contemporary observations (which could be included in a narrative designed to track chronologies of divergence in productivities and living standards between Europe and Asia), global histories of material progress continued to be marred – by three powerful Marxist and Weberian assumptions. First, that Europe's technological and economic superiority over Asia (which became first visible in the eighteenth century and then unmistakable during the nineteenth and twentieth centuries) had evolved gradually, but cumulatively, over several centuries before 1815. Over that time, Europe's political, legal, cultural, and institutional heritage for the conduct of economic activity continued to be exceptionally favorable for the promotion,

first, of Smithian growth, and, following on from that, for technological progress. Third (and in contrast to Europe), other populations lived and worked in more hostile environments and this big ecological fact restrained and often arrested long-term economic development in Asia and Africa – although our knowledge of precolonial African economies remains entirely thin.

Those who follow Weber, Marx, and a tradition of writing that can be tracked back to Montesquieu insist that Europe's competing economies had been on a potentially more promising trajectory for long-run growth for centuries. They emphasize persistent contrasts between European and Asian institutional arrangements, political systems, legal frameworks, cultural conditioning, and religious beliefs, within which economic activities continued to be embedded for at least four centuries before 1815. Cruder Weberians juxtapose the preconditions for long-run Smithian growth that they found operating efficiently in Europe (or rather in some societies in north western Europe) in sharp contrast to Asia, where political, social, familial, cultural, and other negative institutions and beliefs restrained the emergence of competitive markets for commodities, capital, land, and labor.

Their critics, who seem more deeply and widely read in the now massive bibliography of economic and social history dealing with South, East, and South-East Asia, and the Ottoman Empire, have produced samples of data (related largely to population growth, levels of urbanization, balances of commodity trade, yields per hectare and real wages) for selected regions of Asia and the Middle East that at the very least qualify any impression that labor productivity levels and standards of living afforded by European economies to their populations were discernibly (let alone significantly) superior long before the outbreak of the French Revolution. Of course, at this level of 'continental' aggregation, the selection of samples of data for comparative history remains problematical because the Asian economy includes much larger shares of the world's cultivable land, resources, income, and population than early modern Europe.

Nevertheless, economic historians are a long way from offering statistically secure comparisons for average levels of productivity and living standards. Meanwhile, the accumulating volume of research now available on Asian agricultures, industries, trades, credit systems, mercantile enterprise, transportation networks, markets for commodities, and factors of production degrades simplistic Weberian perceptions that Europe alone had evolved the political, institutional, legal, cultural, and religious frameworks required for an effective process of Smithian growth long before other continents into dubious propositions. As Marshal Hodgson observed decades ago, "All attempts to invoke premodern seminal traits in the occident can be shown to fail under close historical analysis." Braudel, Chaudhuri, Frank, Pomeranz, Goldstone, McNeil, Sugihara, Washbrook, and other historians of long-run material change concur. Jones would probably (as he did in Growth Recurring, 1988) continue to revise and reformulate some of the positions he adopted in the first edition of the European Miracle in 1981. From his comparisons of levels and types of development achieved by Europe and Asia for the early modern period, Braudel inferred that "the populated regions of the world faced with demands of numbers seem to us to be quite close to each other." But there is he continued "a historiographical inequality between Europe and the rest of the world. Europe invented historians and made good use of them. Her own history is well lit and can be called as evidence or used as claim. The history of non-Europe is still being written. And until the balance of knowledge and interpretation has been restored the historian will be reluctant to cut the Gordian knot of world history."

That acute observation applies across the entire field because histories of gender and capitalism are but two current areas of controversy that display the unrealized potential of universal history. In truth, it seems difficult to conceive of any grand theme that attracts attention from scholars engaged in writing national and local histories that could not be repositioned within wider geographies and longer temporal periods. For purposes of research, teaching, and debate, comparisons and connections are now the two dominant styles of global history. Pursued with sensitivity, they should deepen our understanding of difference and diversity. In time, they will meet demands for perspective from those trying to comprehend accelerated trends toward interdependence and integration on a world scale and allow for a less ethnocentric appreciation of the manifold achievements of more peoples, communities, and cultures over long spans of human history.

Abstract

In his work on the nature of migration in the late nineteenth century, E.G. Ravenstein highlighted a basic tension between human mobility and the desire of states to control and regulate movement in their own interests. In this article, I apply Ravenstein's insight to the contemporary global migration regime, identifying seven basic tensions that characterize the governance of mobility in the twenty-first century. These include the tension between globalization and territorial sovereignty, policies governing temporary vs permanent movement, states and citizens, citizens and migrants, exploitation and rights, origin and destination countries, and migration and development. Each of these tensions is considered in turn, highlighting the nature and impacts of each on migration and migrants.

The first attempt to systematically describe and explain spatial patterns of migration is to be found in the work of the Anglo-German geographer, Ernst Ravenstein, in the late nineteenth century (Ravenstein, 1885). Ever since, Ravenstein's ideas about migration have served as a jumping-off point in courses, textbooks, and articles on migration and as a source of hypotheses in empirical studies (Grigg, 1977; Skeldon, 1997; Alexander and Steidl, 2012). His basic argument was that observable regularities in human migration could be distilled into seven immutable laws of migration. A critic of Ravenstein noted at the time that migration is "rather distinguished for its lawlessness than for having any definite law" (quoted in Lee, 1966: 47). The idea that there are laws governing migration has long since been abandoned, but this abandonment does not mean that migration is as chaotic and disorderly as Ravenstein's detractors suggested. A vast body of geographical and interdisciplinary research affirms that it is possible to make generalizations and build theories of migrant behavior and explanations for observable patterns, processes, and trajectories of migration (King, 2012).

Ravenstein did concede, in a response to his critics, that the 'laws' of migration were subject to the vagaries of 'human agency' by which he meant government interference. He was pointing to the inherent tension between the propensity of humans to migrate and the regulatory frameworks that seek to control, dam, or divert such movements. The tension between mobility and control was becoming increasingly apparent in the late nineteenth century and became far more acute in the twentieth as states began to erect physical barriers to entry and introduced documentation regimes to regulate entry and exit. Political regimes in many parts of the world (ranging from European colonialism to apartheid South Africa to the Soviet Union to Maoist China) also imposed draconian controls on the internal movement of populations. Ravenstein's insight that there is an inherent tension between mobility and governance, is therefore, worth revisiting in the light of international cross-border migration and globalization in the early twenty-first century. Ravenstein articulated seven 'laws' of late nineteenth-century migration; in the same vein, this article focuses on seven recurrent governance 'tensions' in the early twenty-first century global migration regime.

The first tension is between greatly increased human mobility accompanying globalization and the drive of sovereign states to enforce territorial sovereignty by putting up and enforcing barriers to entry (Collier, 2013). The global migrant population (defined as people living outside their country of birth who have officially or unofficially circumvented these barriers) increased from 92 million in 1950 to 232 million in 2012. Ranked against national populations, the global 'migrant nation' would come in behind China, India, and the United States and just ahead of Indonesia and Brazil. While the number of international migrants may seem relatively small (at just over 3% of the total world population), the desire to migrate across borders (or latent migration potential) is high. The 2007–09 Gallup World Survey found that about 16% of the world's adults would move to another country permanently if they had the chance; this would mean 700 million people worldwide. What holds them back are the opportunity costs of migration and the vast institutional apparatus of gatekeeping – walls, fences, border guards, electronic surveillance, documentation regimes, and virtual 'smart borders' – which constitute formidable barriers to free movement. Many regional economic groupings of contiguous states give lip service to the idea of free movement between member states. For example, the African Union has enshrined free movement as an essential principle of continental integration. Regional subgroupings such as the Economic Community of West African States and the Southern African Development Community have taken a similar stance. However, with the notable exception of the European Union (EU), the implementation of the free movement principle invariably meets with strong opposition from member states who water down the provisions or block them altogether. At the same time, barriers to entry to the EU as a whole (Fortress Europe) are continuously maintained and reinforced (Geddes, 1999).

The second major tension in the contemporary global migration regime is between temporary or short-term and permanent or long-term migration. For much of the twentieth century, international migration was characterized by its permanent or semipermanent character. People emigrated from one country and immigrated to another with little intention of return. Destination countries built immigration

policies around the idea that people would come permanently and that entry could be regulated by moving the bar up or down. One way in which this is done is through points-based systems where potential immigrants score points for various educational, skills, language, and personal criteria. Once the threshold is crossed, immigration is possible for that individual. In this, and like, ways states reasoned that they could pick and choose who they wanted to come and match the new immigrants with domestic labor market needs and priorities. In the first half of the twentieth century, racial or ethnic criteria were fundamental to immigrant selection. However, these were progressively abandoned as the century progressed although they remained in place in countries like South Africa until the collapse of apartheid (Peberdy, 2009). Skills, education, and experience increasingly became the primary criteria for immigrant selection. There were exceptions to the preference of migrants and states to permanent immigration: for example, the Bracero program in the United States for agricultural workers, the Gastarbeiter (guest worker) program in West Germany and the mine migrant labor system in Southern Africa were all designed to ensure that migrants stayed only for as long as their labor was needed. The greatest fear of states importing temporary, often lower-skilled, workers was that impermanence would lead to permanence or, as Castles (1986: 761) put in an 'obituary' on European guest worker programs, they 'inevitably lead to permanent migration in the long run.' States that once feared this 'inevitability' have reembraced temporary migration over the last two decades. The 'resurrection' of temporary migration programs fills short-term needs at the lower end of the labor market and, when tightly regulated, ensures that migrants will go home (Castles, 2006). In Canada, for example, long seen as the epitome of a permanent immigration country, the number of temporary migrant workers now exceeds the number entering permanently as immigrants. In the Global South, circular migration has long been, and remains, the major form of intraregional mobility, Hugo (2009), for example, calculates that there are now at least 15 million temporary migrants within Asia and the Middle East working outside their countries of origin. He identifies nine different types of temporary migration in Asia and the Pacific with varying degrees of legal status, potential to move to permanent residence, ability to be accompanied by dependents, and human and labor rights (Table 1). Some temporary movements take place under formalized recruitment and contract systems (such as migration to the Middle East from countries such as India and Bangladesh and migration to the South African mines from countries such as Mozambique and Lesotho). However, much temporary, circular migration is informal (and oftentimes undocumented) in nature because of the absence of formal policies and channels.

The third tension concerns the contrasting views of states and citizens on the desirability of migration. Almost without exception, the majority of citizens favor exclusionary policies involving restrictions on migration and entry by noncitizens. The World Values Survey asked a representative sample of citizens, what government should do about migrants wishing to come to their country to work (Table 2). At one extreme was the South African citizenry where 78% would like to see strict limits or a total prohibition on entry and only 6% favor a policy that would allow entry to anyone wishing to come and work in the country. The latter figure is consistent with many other citizenries polled: less than 10% of citizens in countries as diverse as Ghana, Brazil, Indonesia, Italy, the United States, and Canada favor such a policy. Lowest of all are Australia (2%) and Germany (5%). Less than half of the citizens in all countries surveyed (except Indonesia, Malaysia, and China) favored an employment-based immigration policy. Over 40% of citizens in major immigration countries such as Italy (57%), Australia (57%), India (46%), the US (44%), and Canada (41%) favor strict limits or a total ban on entry for work. That is a greater proportion of the popular vote than is needed to form a government in many of these countries. In general, states that favor controlled immigration policies are out of step with their own citizens. If citizens could vote on the issue, there would certainly be far more restrictions on movement and much less international mobility. One of the consequences of the tension between states and citizens over the terms and conditions of the entry of noncitizens is that states tend to exaggerate the nature and threat of forms of migration that they do not authorize. Public rituals of denunciation of undocumented migrants and 'bogus' refugees are often accompanied by

Table 1 Typology of temporary migration in Asia and the Pacific

Type	*Status in destination*	*Potential to move to permanent residence*	*Ability to bring family*	*Rights*
1 Less-skilled contract labor temporary migration	Documented and undocumented	Very low	Not possible	Very limited
2 High-skilled temporary labor migrants	Mostly documented	High	Allowed	Substantial
3 Low-skilled seasonal labor migration	Documented and undocumented	Low	Not possible	Very limited
4 Working holiday makers	Mostly documented	Moderate	Possible	Substantial
5 Student migration	Documented	High	Allowed	Substantial
6 Trainee migration	Initially documented but many become undocumented	Low	Not possible	Limited
7 Border commuters/circulatory	Documented and undocumented	Low	Not necessary in many cases	Limited
8 Project tied labor migration	Documented	Low	Possible	Limited

Table 2 Citizen attitudes to migrant entry for work, 2006–07

Country	*Impose complete prohibition on entry (% yes)*	*Enforce strict limits on entry (% yes)*	*Allow entry as long as jobs available (% yes)*	*Let in anyone who wants to enter to work (% yes)*
South Africa	30	48	16	6
India	23	23	25	30
Ghana	18	39	36	7
Zambia	11	30	44	15
Brazil	11	33	47	9
China	8	21	51	20
Italy	8	49	37	6
The USA	7	37	49	8
Germany	7	43	45	5
Indonesia	5	15	72	8
Thailand	5	16	65	14
Australia	3	54	41	2
Canada	2	39	51	8
Malaysia	2	8	72	18

draconian enforcement mechanisms, including raiding homes and workplaces, and arrest, detention, and deportation with a minimum of due process in order to 'purge' national territory of undesirable migrants (Aas and Bosworth, 2013). In the United States, for example, the number of forcible deportations more than doubled from 185 000 in 2000 to 410 000 in 2012. Over this time period, a total of 3.8 million people were deported from the country (Ternes, 2013).

The fourth tension is connected to the third, namely the nature of the relationship between citizens and migrants once the latter are on national territory. One of the fundamental characteristics of national identity in a world of nation-states is that it defines and constantly reinforces the literal and figurative boundaries of belonging, distinguishing between those who belong and those who do not, between insiders and outsiders, between us and them (Amin, 2012). Not only are insiders generally unhappy about policies that do not impose very high administrative and physical barriers to entry by outsiders; they are profoundly ambivalent about the presence of the latter once they do arrive. In Europe, for example, longitudinal data from Eurobarometer surveys between 1997 and 2003 show that 60% of Europeans believed that the limits to a multicultural society have been reached, effectively opposing further acceptance of immigrants into their countries (Coenders et al., 2003). Nearly 40% of participants opposed civil rights for legal migrants and 22% endorsed the deportation of legal migrants, above all, the unemployed. A 2012 Special Eurobarometer Report found that 73% of Europeans feel that non-EU citizens have difficulty integrating because they do not wish to do so. Interestingly, 60% also acknowledge that non-EU citizens faced discrimination in the EU. When intolerance and hostility is based purely on the 'foreignness' of the migrant, xenophobia exists. Xenophobia consists of highly negative perceptions and practices that discriminate against noncitizen groups on the basis of their foreign origin or nationality (Crush and Ramachandran, 2010). It affects all categories of migrants, immigrants, refugees, and asylum-seekers. Xenophobia is perpetuated through a dynamic public rhetoric that actively stigmatizes and vilifies migrants by playing up the 'threat' posed by their presence and making them scapegoats for social problems. Xenophobia takes on various forms but is usually accompanied by a powerful stigmatizing and stereotypical set of myths about migrants (Lucassen, 2005). Xenophobia is not simply an attitudinal orientation, however. Hostile and skewed perceptions of migrant groups generally go hand in hand with discriminatory practices and poor treatment of such groups. Acts of violence, aggression, and brutality toward migrant groups represent extreme and escalated forms of xenophobia. Xenophobia is traditionally associated with right-wing political parties in Europe, but its pernicious influence extends well beyond Europe. The present-day surge in intolerance and xenophobia in the South can be seen in migrant-receiving countries as diverse as South Africa, India, Malaysia, Thailand, and Libya (Crush and Ramachandran, 2010). South Africa, which has one of the most xenophobic citizenries in the world, was rocked in May 2008 by nationwide mob violence against migrants in which 60 people died, 600 were seriously injured, and over 100 000 were driven out of their communities.

The fifth tension relates to the extension and denial of rights to migrants. States and citizenries display a consistent pattern of resistance to according the same rights to migrants that are enjoyed by citizens. As a result, migrants are generally vulnerable to a range of abuses by governments and employers. The poor treatment of migrant workers, especially those in temporary work situations, has been well documented worldwide. The latest example concerns the situation of migrant construction workers in Qatar hired from various countries outside the region to build venues for the 2022 FIFA World Cup. Amnesty International's (2013) expose, *The Dark Side of Migration*, systematically documents widespread discrimination against a general backdrop of discriminatory attitudes toward migrant workers. These abuses include not being paid for long periods of time, inhumane working conditions, and squalid living arrangements. According to Amnesty International many migrants are in "severe psychological distress due to the treatment they had received and their sense of powerlessness to resolve their own situations." At a global level, the struggle for migrant rights pits migrants, migrant organizations, and human rights advocacy groups against governments and employers. The general attitude of states toward rights for migrants is evident in the tortuous history of the 1990 UN International Convention on the Protection of the Rights of All

Migrant Workers and Members of Their Families (ICRMW). Cholewinski et al. (2009) characterize the ICRMW as "a vital instrument to ensure protection of migrants' human rights" and yet it has been treated with 'marked indifference' by states. In 20 years, the Convention has been ratified by only 41 states, none in the North and no major migrant-receiving countries. By contrast, the 1989 UN Convention on the Rights of the Child was ratified by 193 states within 5 years. A global survey of policy responses to the ICRMW revealed a wide range of reasons why states refuse to ratify the Convention. There are concerns about the costs of implementation and, in some cases, specious arguments (made by countries like Canada) that the Convention is unnecessary because domestic legislation provides all the same protections, making ratification redundant. The overall message is clear, however. States do not want to accede to any kind of international normative framework that would potentially divest them of complete discretion over how they choose to treat migrants and what rights they seek to provide and deny.

The sixth tension is between countries of migrant origin in the South and countries of migrant destination in the North. This tension takes various forms but has been most intense in relation to the 'brain drain' of skilled migrants from South to North (Kapur and McHale, 2005). Tanner (2005) argues that attitudes toward brain drain in countries such as Canada are "at best unconscious, at worst indifferent." The actual impacts of the brain drain on countries of origin are hotly debated. As Goldin and Reinert (2006: 183) then of the World Bank suggest: "While high skilled migration in sectors such as IT seems to have played an integral role in helping spur economic development in a few source countries, high-skilled migration in other sectors – health and medicine, in particular – have done considerable damage to source countries." Most absence effects discussed in the general literature are negative. These include larger skill premiums that increase inequality; fiscal losses through lost tax revenue; diminished scale economies; loss of role models and spillover knowledge from most-skilled to lesser-skilled individuals; loss of entrepreneurs; and changed comparative advantage (Kapur and McHale, 2005; Tanner, 2005). Most attention has been paid to the negative impact of the migration of medical professionals on countries of origin. These countries, with underresourced health systems, the highest rates of infant mortality, and ravaged by infectious disease, cannot afford the loss of health care personnel. In Ghana, for example, half of the physician graduates between 1985 and 1994 had left the country within 4.5 years, and three-quarters had left within 9.5 years. The whole 2002 graduating class of doctors had left or planned to leave. Awases et al. (2003) provide information on reasons for and patterns of migration (with reference to doctors, nurses, pharmacists, and midwives), effects on health care, and policies undertaken in six countries for the period 1991–2000. They conclude that the skilled migration of health professionals from Africa has adversely affected the quality of care to the poor, given that there are fewer personnel available, heavier workloads, fewer drugs, and performance of duties by underqualified personnel. Overall they conclude that "the importance of the impact of the loss of human resources in terms of skills and numbers in relation to the total size of the health workforce cannot be overemphasized." Among the demands of countries in the South are a cessation of recruiting, closing of the doors to skilled migrants from developing countries, and financial compensation for the loss. The countries of the North have consistently rejected these demands.

The seventh, and final, tension concerns the relationship between migration and development (Skeldon, 1997). Global policy debates about this relationship have intensified dramatically since 2000. Key moments include the appointment and report of the Global Commission on International Migration, two UN High Level Dialogues on International Migration and Development (in 2006 and 2013), the establishment of the annual Global Forum on Migration and Development in 2007, and the formation of the interagency Global Migration Group. The relationship between international migration and development is often conceptualized as a 'nexus' to denote the reciprocal nature of the linkage: migration has impacts on the development process; similarly development can influence flows of migration. Most commentators agree that the links are exceedingly complex and hard to unravel. Three general perspectives on the nexus can be identified in contemporary policy debates: (1) migration has a positive impact on the development of countries of origin in the Global South; (2) migration has negative implications for the development of those countries; and (3) the relationship between migration and development is a 'balance sheet' of pros and cons. de Haas (2010) argues that since the 1960s, the pendulum has swung backward and forward between optimistic and pessimistic views of the relationship. The current, post-2000, phase of optimism focuses on two main features of the contemporary global migration regime. First, there are the massive global flows of remittances from migrants to their countries of origin. In 2013, these flows are estimated at USD410 billion or three times the amount of Official Development Assistance. Second, many migrants maintain close social and economic ties with their countries of origin that can have development-related implications and impacts. Migrants are increasingly seen as diasporas, and countries of the South are actively attempting to engage 'their' diasporas in development activities (Mohamoud, 2010). Another, contentious, aspect of the relationship is whether development leads to a decline in migration. One line of argument is that poverty causes migration and that development will therefore dampen migration flows. In the case of the EU, the particular policy outcome is that the 'root causes' of migration should be identified and development assistance targeted to reduce 'migratory pressure' on Europe. There is little evidence that this approach works or is worth pursuing. Indeed, many analysts argue precisely the opposite that development may actually increase rather than decrease migration (de Haas, 2007; Bakewell, 2008).

Researchers are active in all seven of the tension areas identified in this article. However, three are particularly relevant to understanding the geographies of international migration and are consistent with Ravenstein's concern with how state actions 'interfere' with migration flows. The first concerns the massive effort – measured in resources, personnel, and surveillance technologies – expended by states in the physical and symbolic construction and reinforcement of barriers to movement, the strategies of circumvention by migrants, and the coercive efforts by states to 'cleanse' their territories of

'outsiders' (Fassin, 2011; Mountz et al., 2013). The second concerns the flow of skilled migrants from the Global South to the Global North, which is facilitated by state interventions in the form of proactive immigration policies and recruiting. These policies and their impacts are well studied. More controversial is the growing debate about impacts between 'brain drain' and 'skills flow' researchers (Mills et al., 2011; Clemens, 2013). The latter group takes issue with virtually every aspect of arguments critical of the brain drain – including the very term itself – and contend that the downstream benefits of migration to countries of origin easily outweigh the loss of skills. This debate has rapidly become an ideological contest with divergent policy prescriptions but little hard evidence either way. And third, with regard to the migration and development relationship, there is a need to break with the pervasive view that only migration from the South to the North has development impacts in the South. South–South migration is an increasingly important global phenomenon, and its impacts on development in both countries of origin and destination is starting to emerge as a major research issue (Anich et al., 2014).

Global Positioning System

Mauro Salvemini, Sapienza Università di Roma, Rome, Italy

Abstract

The contemporary society benefits from using global positioning system (GPS) for locating almost everything in the world. Data originated by GPS technology are easily usable and can be integrated in a large variety of systems for purposes ranging from safety and territorial intelligence to land use change detection, from navigation to mapping, from social networking to rescue intervention. Many personal devices, such as mobile phones, contain GPS microchips allowing the common user to play the role of surveyor and produce an enormous amount of geographic data and georeferenced data. GPS is the electronic device, together with the mobile phone, which underpin the paradigm of a liquid society.

A global positioning system (GPS) is a radio wave receiver used to provide coordinates that give the exact position of an element in a certain space. The radio waves are emitted by a constellation of orbiting satellites, which function as a reference system for GPS. In reality GPS is based on technology, which is capable of reaching very high levels of precision, even to less than a millimeter, if certain aspects of the technology are exploited and if the period of observation can be maintained for a sufficient amount of time. GPS technology is deeply influencing contemporary society. Only recently have mobile phones and tablet computers been equipped with GPS chips; as well, many new car models and other public and private transportation systems now have built-in navigation devices. The stand-alone GPS with a built-in system for managing downloadable maps is now so affordable that it has become the common companion of travel, leisure, and sport time.

GPS gives human beings the ability to access the geographical coordinates of any object on the earth's surface and to increase our knowledge of the object's characteristics with geographical data, collected in real time and directly from the field at very low cost.

Along with extensive and easy use of location-based data and linked information and images, problems arise: the limitation of privacy and a reduction in people's orientation abilities are prime examples. On the one hand, personal wearable devices such as glasses and watches may give directions, show and record images, and interact with the owner because of knowing, through GPS technology, the spatial coordinates of the user. On the other hand, sharing a person's specific location on the web through social networks or through the street view, his house and parked car, or even himself entering garage is a potential threat to privacy.

GPS helps solve three fundamental questions that from the beginning of time humans have sought to answer: where am I now, where am I going next, and what is the best route from here to there? The observation of the sun and stars, and then later the use of the compass, the sextant, navigational maps, and charts of the heavens have all been essential aids and instruments in this never-ending quest. GPS is the most recent and easy to use contribution to this search and changes the expertise needed to find in the real world and to map the geographic coordinates of everything; in short, everyone can produce geographic information; anyone can generate the path, street, point, and area or location of any object. As a result, volunteered geography (VG) is steadily developing a large database of volunteered geographic information published on the WWW by user communities that subscribe to the open-data geographic information approach. While changing the praxis of having geographic information available for use by citizens, VG is affecting, differently in various nations, the authoritative process of public administrations providing maps for institutional, legal, and financial purposes. The provided data and map precision are consistent parts of government-provided official cartography; the use of GPS to create maps does not automatically solve issues of data accuracy or data transformations. GPS helps people primarily to move about in space by providing their location relative to other objects, which most often have fixed locations but can also be mobile. The semantic difference between location and position has to be taken into account when analyzing physical and social – cultural phenomena.

Origins and Instances

Over the years the need to answer to location questions has been the driving force behind the development of many civil and military applications. During World War II, one of the nations in combat realized that, even if it managed to build warships relatively rapidly, it was much more difficult to find suitable commanders for the ships. Such positions required candidates with a high level of experience, especially for mapping the ship's course. From this dilemma long-range radio navigation (LORAN) was born, a system essentially for use at sea, based on the reception and phase difference of radio waves transmitted from two antennae. These two stations transmitted a continual flow of coordinates to navigators equipped with the correct passive antenna, which they then used to pinpoint their exact location on the earth's surface. This facilitated the commander's decision making enormously, as he knew the ship's position at any time and, by using additional electronic aids or by simply mapping the points already crossed on a nautical chart, also knew exactly where the ship was headed. The GPS was the natural evolution of LORAN.

At any given moment and point in the area covered by the system, GPS is capable of providing the three-dimensional

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72022-8

coordinates (x, y, z, or latitude, longitude, and height). Rapid progress in electronic component design, has miniaturized GPS equipment to the extent that any personal wearable device can contain GPS and can provide the wearer with her exact position, the route she followed, and where she has to go.

In flights, ships, trains, buses, and cars, a screen displays a schematized map of the territory and, using GPS, a pointer indicates current position, path, and, among other information, how much time remains before reaching the destination. Users draw comfort from knowing where they are and when they will arrive. They may be able to use the features mapped on the screen to recognize physical characteristics of the surrounding territory and look to specific points of interest. Increased safety can be an added benefit of GPS use.

Aside from the passive and temporary use of GPS to determine position, route, and destination, the system is also important for activities with long-lasting and consequential effects. The most important example is the use of GPS in cartographic, topographic, and geodetic practice and research, and, by extension, to many forms of inquiry in social science. Through the use of this device, mapping becomes easy even in difficult mapping situations such as *favelas*, migrant communities, and natural constituents (forest, swamps, polluted areas, etc.), which had long posed challenges for cartography and thematic mapping. With GPS, the earth's surface becomes an enormous digitizer, and any point can be identified instantly by its three-dimensional coordinates and archived in a suitable information system, potentially increasing the intensity of sampling events and objects in space and time by several degrees of magnitude. Such measurements affect research and practice in archaeology, economics, geography, planning, and sociology, as well as in the natural sciences. By determining precise coordinates of points on land or on the surface of water, GPS makes it possible to update maps by locating physical and social features from which GPS gathers data instantaneously and/or detecting changes that have occurred in reality but have yet to be recorded (e.g., new construction, physical changes in the environment, transient events, or those in constant transformation such as people, vehicles, coastlines, woods, glaciers, and so on). GPS plays a unique role in disaster and relief management giving exact location of people, settlement components, infrastructures, and disaster origins. For example, volunteer citizens used GPS to map the Haiti earthquake zone in 2010 as they have in many other community-originated initiatives during and after disasters such as flooding, fires, and hurricanes.

The General Principles of GPS Functioning

GPS receivers use radio waves to determine positional coordinates. The radio waves are emitted by a constellation of orbiting satellites, which function as a reference system for GPS. The constellation consists of 24 satellites, which are located in six orbits, inclined at an angle of approximately 50°, at a height of around 20 000 km. Known as NAVSTAR, the constellation is the property of the US government and is controlled and managed by the Department of Defense. The orbits and the distances between satellites are organized in such a way that, ideally, every point on the earth's surface can be seen by at least five satellites at the same time, although this is not always the case in practice. The GPS carries out the triangulation of three satellites visible at the same time above the horizon, measuring the distance that separates it from each of these by calculating the time between each satellite (transmitter) to the GPS itself (receiver) using precise time signals emitted by the satellites. The triangulation allows the GPS to determine the latitude and longitude, though a fourth satellite is also necessary to determine a third coordinate giving the height at which the GPS receiver is located. To measure the time required by the signal to travel the distance from each satellite to the receiver, it is essential to use extremely precise equipment to transmit the signal, to calculate the time lapse, and also to pinpoint with extreme accuracy the position of each satellite in space. To this end each satellite is equipped with an atomic clock, and its position is constantly monitored and regulated by a series of earth stations.

In place at the end of 1990, GPS achieved initial operational capability by a full constellation (24 satellites) by December 1993, having been massively used for the first time during the Gulf War, and was able to provide the standard positioning service. Since 1993, the GPS system has been the object of several US governmental initiatives.

It is essential to consider the problem of errors incurred by external agents when dealing with instruments as sophisticated as the GPS. To determine the exact time the signal takes to reach the GPS receiver, it is also necessary to understand all the modifications and distortions the signal may undergo while passing through the ionosphere and the atmosphere. The causes of error and/or the malfunctioning of the system are varied, and can range from atmospheric conditions to the position of the satellite constellation in the sky and their visibility from the receiver. The location of the GPS receiver itself may cause problems. For example the receiver may be unable to detect a satellite if it is located under a canopy of thick vegetation or in a city canyon, where its horizon may be modified by the height of surrounding buildings.

Those managing the system itself may introduce certain deliberate errors. GPS, for example, has been subject to selective availability (SA), a randomized error deliberately incurred in the time signal from the satellites to degrade the positional accuracy of the receiver to the order of 10–100 m. Acting on a declaration made in 1996, on 1 May 2000, US President Bill Clinton announced the end to the use of SA in GPS, with the immediate effect of increasing and encouraging the use of GPS for civil and commercial purposes throughout the world. In fact, the demand for GPS precision is high among civilian users. Every context has its own GPS accuracy measurement needs. In an urban situation for example, the user may wish to know what side of the road he is on or which traffic lane to be in, and in the development of technical charts, cadastres, and engineering plans, the precise coordinates of the point on the ground are needed in order to represent it on a topographic map; accuracy needs increase even more in geodetic applications. In reality, GPS is capable of reaching precision of less than a millimeter, if certain components of the technology are exploited and if the period of observation can be maintained for a sufficient length of time.

The precision of GPS measurements is also influenced by factors such as whether the station is mobile or fixed (at least

for the time being) and whether the receiving station functions alone or in connection with other stations. The ability for a station to operate in conjunction with at least one other fixed station provides optimal precision. This technique is called differential GPS, and it is based on the registration of signals transmitted by the satellites and simultaneously picked up by a fixed or base station (master), whose precise geographical coordinates are known, and by a mobile station (rover), located anywhere within a range of around 150 km from the master station. Processing the data received by the master station eliminates the errors in reception by the rover. Local public administrations have been aware of the social demand for and usefulness of GPS data and have created local master stations as a public service to support user communities.

GPS models suitable for specific applications are available in professional and consumer markets; some are equipped to receive radio signals and different location signals produced by specific systems such as the Russian-developed GLONASS. The issue of automatic location detection has reached such relevance during these years that China, India, and Japan have developed their own systems covering various areas. The Galileo global system developed by the European Union and other partner countries is planned to be fully deployed by 2019. Societal needs are important in Galileo deployment, which is designed to support industrial development and social progress.

GPS and other mentioned positioning systems do not work indoors because the signals encounter difficultly being received in buildings, built areas, and closed spaces. This limitation is presently solved by indoor positioning systems, which by using different or combined technologies enable one to survey the location of objects indoors. This technology is expected to develop rapidly along with the evolution of mobile devices (e.g., mobile telephones) and the wide use of wireless networks and sensors while the social implications discussed below will increase.

The Relationship between GPS and Information Systems

The most relevant aspect of GPS to the information society in 2013 is its ability to provide the geographical coordinates of any object on the earth's surface and to increase our knowledge of the object's characteristics with ancillary data, collected in real time and directly from the field, at very low cost. Without doubt, the geographical or location component is an essential part of current databases and is generally deduced from a classification of objects by name (city, road, house number, etc.) or is represented by the cartographic coordinates of the single object gathered from maps (e.g., the centroid of a manhole cover, telephone or electricity pole, the axis of a water or gas pipe). In each case the geographical component, if obtained by traditional means, is approximate, expensive, or unreliable in relation to both time and space: Time, because things can change from one moment to the next (an electricity pole can be moved relatively rapidly in reality but not so rapidly on the charts representing it); Space, because an element located in a certain territory undergoes continual transformation; the shores of a lake or a coastline for example can be modified by environmental factors.

Conferring a geographical address on each item of data allows for the application of the analytical, inquiry, and management functions of a geographic information system (GIS). Real-time availability of the geographic address means that the spatial analysis can be carried out instantaneously in the field. Typical spatial analysis functions include: investigating relationships of proximity to, or distance from the object, superimposition of information layers, the search for the shortest or any route that satisfies specific conditions, identification of spatial environments that group objects with specified characteristics, monitoring transformations of the object, and so on. Spatial analysis is based on the amount and the accuracy of geographic data and their attributes. GPS is dramatically increasing the possibility to easily input data into databases and on the other hand it is enabling the descriptive attributes of real world to be geographically referred. This makes spatial analysis substantially more efficient. Typical functions of inquiry analysis are those that identify the information linked to an object by selecting that object from a spatial database rather than selecting it from the alphanumeric database and obtaining thematic maps ad hoc. Typical functions of information system management are those that enable continuous updating of the constituent elements by refreshing the data and integrating the geographic database whenever necessary.

Constant information flux poses a major problem in an information-dependent society, and updating coordinates in three-dimensional space is extremely challenging. Connecting GPS to other techniques helps solve this problem. For example, we can consider digital cartography, necessary for a decision-making process in a territorial or urban context. Decision makers rely on territorial information systems and the digital cartography that are archived in their databases. But what happens when digital cartography no longer reflects reality? A city or region can change very rapidly, and if the digital map is not updated, the information system using those spatial data will no longer be very useful. Invalid information may be merely inconvenient, or it can lead to serious social or legal complications. GPS helps greatly, but in addition to the maps that need continual updating, the geographic addresses of data points are particularly useful in social science. Among these are census tracts, political districts, administrative units, pollution zones, and epidemiological information, or research concerning traffic and movement. More controversially we may monitor individuals.

Examples of the Use of GPS and Its Social Implications

The development of GPS and its diffusion is a step toward having geographic address (x, y, z coordinates in space, or longitude, latitude, and height) and exact time as a component of any type of information. GPS equipment is widely used by utility companies to identify the components of their networks (poles, pylons, wells, technical components, etc.) and has long been used to identify the position of submarine oil wells from offshore oil platforms. Additionally anyone, at any moment in

time, can visualize the location or destination of any vehicle transmitting its coordinates to be collected in real time by GPS. For example when mounted on a public bus, a GPS can supply immediate information on the vehicle's location, the journey time, and anything else that is necessary to satisfy the needs of the driver, passenger, or manager alike. For some time insurance companies have been using this system to reduce the incidence of car thefts, and traffic management systems, publically available on WWW, now collect data from cars, which constantly communicate their own location. Car manufacturers now equip cars with navigators: electronic navigation systems containing a digital map of the area in which the car is traveling and on which the positioning and movement of the vehicle itself is traced, thanks to the continual tracking of its location through GPS. Integrated with other systems, GPS permits a vehicle to proceed automatically, without the aid of the driver or pilot. Systems already exist in marine and aeronautical applications that are capable of functioning as autonomous autopilots. In agriculture so-called precision-farming is transmitting accurate GPS-produced data to automatic farm machinery. Exact details of military applications are not available to public knowledge, but it is easy to guess that the same basic technology is used with more sophisticated developments. An internal GPS in a cellular phone provides the user with his or her exact coordinates, and can be used to visualize the location of similarly equipped phones in social network systems. Such devices are in regular use at large conventions to facilitate (or avoid) meetings. The same device alerts emergency services to incidents on lonely stretches of unfamiliar road or, worn as clothing, GPS may guide the sight-impaired or guard children against becoming lost. All fields that use geographic coordinates may derive benefits from the use of GPS.

As mentioned above, two principal problems are linked to the use of GPS: a reduction in the capability of orientation and limitations on privacy.

The problem of the reduction in the capacity to orientate oneself is due in part to the use of digital coordinates, rather than analog information such as: go to the square, turn right at the newsstand, go straight on to the white building, etc. With GPS a person can supply a visitor with the coordinates of his or her position by simply pressing a button; the visitor receives the coordinates and transfers them to his autopilot or navigation system, and the vehicle navigator directs the visitor to the desired location. Nothing will remain in the visitor's memory, unless he has paid attention to the features of his route and not simply paid attention to the screen. It is a question of personal choice whether to learn to navigate in one's environment or to rely wholly on digital assistants. The so-called systems of computerized street view together with GPS use or the use of GPS-originated coordinates may help to understand, analyze, and better use space, especially in a city environment; nevertheless navigation through these systems does not substitute for the reality experienced by walking.

The privacy problem is a crucial aspect of the use of GPS in society. The power of knowing at any given moment the location of someone equipped with a GPS can be a source of enormous security in certain situations such as the occurrence of an accident. But knowing someone's movements is potentially a great intrusion on personal privacy. For example, with GPS and GIS we could discover the shop, office, or facility someone is currently visiting, or recreate their activities during the past 24 h or longer. The surveillant society is the flip side of the information society. Separating valuable monitoring from unwarranted intrusion into personal privacy, and deciding who has the power to distinguish between them, poses a major challenge to society.

Summary

GPS systems and GPS receivers (integrated in mobile phones, tablets, cameras, watches, and even glasses) have become practically ubiquitous. Citizens are pushed to contribute through the volunteered and open-source paradigm to survey GPS data, to share geographic data, and to deliver data to the WWW making them available to web community.

Some of the benefits deriving from the enormous quantity of publicly originated GPS data have already been realized and some others are expected to emerge as the WWW develops together with communication systems.

Cartographers, engineers, planners, archaeologists, and geographers have drawn enormous advantages from the active use of GPS and will continue to enjoy the benefits of a new technology that allows for rapid and much less costly collection and updating of geographic information. The integration of engineering designs realized with CAD, digital mapping, and GPS, introduces the possibility of devices capable of elaborating designs for civil engineering and proceeding through interactive surveys, to the construction of roads, buildings, etc. GPS also integrates well with the analysis of data that have been collected via satellite for the observation of the earth, in that it allows for the exact identification of the coordinates of specific features on the satellite image. Social applications range across all walks of life. Inevitably, as with all technological innovations, its use should be evaluated critically, and the limits of its appropriate use determined.

Global Public Policy

Inge Kaul, Hertie School of Governance, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although we live in a globalizing world there exists so far no systematic conceptualization of global public policy. Accordingly, this article explores the question of whether such a policy has emerged in practice. It finds that qualifying initiatives do exist, and in rising numbers, but that they have not yet coalesced to form a new, identifiable policy strand. The conjecture that the article offers for further research and debate is that defining a sovereignty-compatible rationale for global public policy is the critical missing link. This will first require well-framed proof that in global-issue areas marked by interdependence, fair and effective international cooperation is in states' enlightened self-interest and, second, consensus on a notion of 'smart' sovereignty, that is, an exercise of sovereignty that seeks to combine the pursuit of national interests with respect for the sovereignty of other states.

Awareness is growing among policy analysts that there exists no well-established concept of global public policy (Reinicke, 1998; Severino and Ray, 2010; Stone, 2008). This despite the reality that more and more policy challenges are of a global, border-transgressing nature – just think of the excessive volatility in international financial markets witnessed since 2008 or of global climate change. Indeed, examples of challenges that pay no heed to national borders are rampant; among them are also illicit international trade, an accompanying rise in crime, cross-border migration, Internet governance, and the risks of cyber-war, not to mention the persisting challenges of nuclear proliferation, communicable diseases, and global inequity.

So, how are these policy challenges actually being addressed? Could it be that a new type of policy, a global public policy, has evolved? Perhaps its development has progressed incrementally and in an ad hoc fashion, pushed by a series of crises that have called for exceptional, innovative measures? If so, what are the distinctive features of this global public policy? And what might it take for theory to catch up with policy practice?

These are the questions at the center of this article.

Section How to Recognize Global Public Policy outlines the approach. It suggests that to recognize global public policy when we see it, we need an analytical grid that helps us to spot relevant phenomena. Accordingly, and considering that many, if not most global challenges possess the characteristics of a global public good, it proposes to define the purpose of global public policy as the provisioning of global public goods. Furthermore, taking into account the particular governance challenges that these goods pose, as well as current trends in global power relations, Section How to Recognize Global Public Policy identifies four functions that a global public policy would need to fulfill, namely (1) averting risks of dual – market and state – failure in the presence of global public goods; (2) promoting global fairness; (3) facilitating the actual 'getting to the good'; and (4) supporting global systemic sustainability.

Drawing on select empirical evidence, Section Global Public Policy: A Reality? then reviews recent policy responses to global challenges to determine whether those appear to have contributed to any of the four functions. The review reveals that qualifying initiatives exist, and in rising numbers. Perhaps it is this fact – the take-off of global public policy at the operational level – that gives rise to sovereignty concerns and inspires, at the same time, a reluctance to cooperate especially among state actors.

As Section The Missing Link: A Sovereignty-Compatible Rationale for Global Public Policy argues, this leads to a policy trap: the sovereignty paradox. The more state actors shy away from international cooperation to shield their sovereignty, the more often they fail to meet global challenges, losing, piece-by-piece in these failures, the very thing they seek to protect – and allowing problems to linger and assume crisis proportions.

Thus, what it might take for policymakers and their constituencies to break out of this paradoxical situation might be the fashioning of a sovereignty-compatible rationale for global public policy.

In more detail, the argument follows.

How to Recognize Global Public Policy

The term 'policy' is being used here in a broad sense. It denotes all the actions taken to achieve desired goals. Accordingly, we should first specify the overall purpose and functions of a global public policy, taking into account the nature of the challenges to be addressed and what might be needed to address them under the present policy-making realities.

If we define the overall purpose of global public policy as helping to resolve global challenges, we ought to bear in mind that many, if not most of those challenges possess the properties of global public goods or might, as a corrective step, require inputs with these attributes. Moreover, these challenges need to be addressed amidst shifting power relations, specifically the intensifying trend toward multipolarity and a balance between state and nonstate actors that has, in recent decades, tipped in favor of the latter.

Taking these factors into account, it appears that a global public policy would, among others, need to perform the following four functions.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.75019-7

Function 1: Averting Risks of Dual Actor – Market and State – Failure

As Box 1 notes, the defining property of public goods, including global public goods, is their publicness in consumption, that is, they affect everyone, for better or worse. This characteristic poses an important risk for the provisioning of these goods, as it may tempt individual actors into free riding. They may conceal their true preferences for these goods, waiting for others to step forward and provide them. Then, when the goods emerge in the public domain, the free-riders may enjoy them, too – free of charge.

Because some individual actors succumb to such free riding temptations markets are likely to fail in ensuring an adequate provisioning of public goods. Therefore, as economists say, the existence of public goods constitutes a condition of market failure. As the risk of free riding tends to increase with the number of actors involved, global public goods are especially prone to underprovision due to market failure.

At the national level, the state can intervene and potentially correct public good-related market failure due to its unique ability to create incentives. At the international level, however, there is no full equivalent of state institutions. Moreover, when appearing internationally, state parties, for the most part, pursue national interests which may or may not overlap with global concerns. Hence, internationally, they, too, are actors with particularistic – quasi-private – interests, and, as studies on international cooperation have repeatedly shown, they, too, succumb to free riding temptations.

This implies that global public good-type challenges run the risk of dual actor failure: market failure and state failure. (The type of state failure identified here is not to be confounded with the types of government failure that public choice scholars tend to focus on, namely the self-interested behavior of politicians and bureaucrats. The state failure referred to here has systemic roots that lie in the fact that the present world order is composed of individual sovereign nation states.)

Thus, one function of global public policy would need to be averting or at least minimizing the risk of such dual actor failure in the presence of global public goods, most notably the risk of state failure. Preventing the latter is of special importance, as effective multilateral cooperation is often needed for states to 'tame' globalizing markets, as well as themselves.

Function 2: Promoting Global Fairness

Alone, function 1 might not suffice to bring about the level of willingness to participate required to make cooperation work effectively under today's polycentric conditions, that is, without pressure from a hegemon or club of major powers. Under these conditions, an important incentive for actors to engage in a public policy initiative is that the engagement clearly 'pays' – economically, politically, or otherwise.

Considering the wide differences and disparities that exist in the world, the most feasible way for parties to perceive international cooperation as fair and legitimate is perhaps process fairness: to afford all concerned an opportunity to have an effective say in matters that affect them, while striking a balance between representativeness and decision-making efficiency.

Risks of policy stalemates or even breakdowns due to irreconcilable differences in the negotiating parties' preferences could perhaps be reduced by coupling process fairness with positive-sum thinking. The latter approach is characterized by willingness to seek mutually beneficial bargains and broadly share the gains from cooperation among the stakeholders, internationally and nationally. This could be in the parties' enlightened self-interest because, under conditions of openness, unresolved global challenges continue to roam the global public domain, potentially affecting all or any one country or actor group haphazardly.

Box 1 Introducing public goods and global public goods.

Standard economic theory distinguishes between two main categories of goods: private goods and public goods.

Private goods are goods that can be parceled out and made excludable so that clear property rights can be attached to them.

Public goods, by contrast, are goods that are nonexcludable, meaning that the goods' effects (benefits or costs) are there for all.

If a good is nonexcludable and nonrival in consumption so that one person's use of the good or one person's being affected by it does not diminish its availability for others, the good is said to be pure public. Examples are the light of a candle and peace and security. If a good possesses only one of these properties it is impure public. The atmosphere, for example, is nonexcludable but rival in consumption, because unrestricted pollution can change its gas composition and contribute to global warming. Patented pharmaceutical knowledge illustrates a nonrival good, whose use has, at least for a limited period of time, been made excludable. So, it, too, falls into the category of an impure public good.

The public effects of a good can be of different geographic – local, national, regional, or worldwide – reach, and they can span across one generation or several generations.

Global public goods are goods whose benefits or costs are of nearly universal reach or potentially affecting anyone anywhere. Together with regional public goods they constitute the category of transnational public goods.

Important is to emphasize that, in the present context, the term 'good' has no value connotation. It is used as a short form for the goods or products, as well as services and conditions that exist in the public domain.

Also, in most cases, publicness and privateness are not innate properties of a good but the result of a social or political choice. Therefore, it is important to distinguish between the potential and *de facto* publicness of a good. For example, land can be freely accessible to all; or it can be fenced in, be made excludable.

Globalness is a special form of publicness, and in most cases, it, too, results from a policy choice, for example, a decision to promote free trade or financial liberalization. Thus, while some global public goods are naturally global and public like the sunlight, many others are human made, including the international communication and transportation systems or the goods of communicable disease control, financial stability, or peace and security.

Source: This box draws on Kaul and Mendoza (2003). The interested reader may also wish to consult Barrett (2007) and Sandler (2004).

Hence, a desirable further function of global public policy would be the promotion of process fairness coupled with positive-sum thinking.

Function 3: Facilitating the 'Getting to the Good'

While publicness in consumption is the defining property of a public good, many goods are also public in provision. They require state or nonstate actors, who wish to alter the provision status or form of a public good, to pursue the cooperation of others. This holds especially for global public goods. In many cases, their provision path is multiactor, multisector, and, importantly, multilevel.

As Figure 1 shows, goods of this type emerge from a summation process. National policy measures and outcomes – provided in an internationally concerted manner – tend to be the main building blocks, complemented, as and if needed, by international building blocks such as an agreement defining the shared goal to pursue or an organization through which parties undertake pooled initiatives.

Consequently, effective issue management and result orientation, that is, actually producing the desired good, can be seen as a third key function of global public policy. This entails, in particular, recognizing the provision path of global public goods as a new, added policy space that may partially overlay the established policy spaces defined by geographic criteria, economic sector, and actor group. In many instances, meeting a global challenge calls for inputs from all of these other spaces – in a multiactor, multisector, multilevel approach, and, hence, for an issue manager or anchor institution to facilitate the pulling together of these diverse input threads.

Function 4: Supporting Global Sustainability

Alongside the global issue space there is another new public policy realm which a global public policy would need to take into account: the global public domain.

Various global public goods may have entered the global public domain at different times, owing to newly arising challenges or swings in economic thought and evolving global power balances. Moreover, they may have been negotiated in different venues and by different actor groups. Thus, conflicts between them may exist (Petersmann, 2011), with the result that overall global efficiency and equity suffer and opportunities for progress are constrained.

Also, as recent studies on future global trends show (e.g., WEF, 2011–2013), more and more global challenges are lingering in a state of serious underprovision. These are beginning to interact and form risk clusters of potentially catastrophic impact.

Hence, the fourth function of global public policy would be global risk and opportunity management.

❶ **Incentives**
Encouraging actors to deliver direct and indirect inputs or to change behavior to account for social concerns

❷ **Opportunity**
Offering households and firms the possibility of consuming goods and services that generate externalities that enhance the provision of the public good

❸ **Demand for international cooperation**
Reflecting national preferences for cooperation beyond borders

❹ **Political Pressure**
Lobbying governments to fund or deliver goods

❺ **Consumption**
Consuming goods and services made available to enhance the provision of the public good

❻ **Coercion**
Compelling individuals and firms to change their behavior to account for social concerns

❼ **Externality**
Emerging as a result of individual action

Based on the assumption that the good follows a "summation" aggregation technology

Figure 1 Provision of global public goods. Source: Kaul, I., Conceição, P. (Eds.), 2006. The New Public Finance: Responding to Global Challenges. Oxford University Press, New York, p. 14.

Do we see empirical evidence that these predicted functions are actually being performed? If so, what operational forms do they take and who is performing them?

These are the questions explored in Section Global Public Policy: A Reality?

Global Public Policy: A Reality?

Even a cursory look at recent policy practices in global issue areas reveals that many qualifying initiatives exist. So far, however, as the following facts and figures suggest (and discussed in more detail in Kaul, 2013), they occur in a relatively spontaneous, ineffectively coordinated, even muddled way. They are being undertaken by myriad state and nonstate actors, acting alone or in association with others. But, before describing the existing response pattern in more detail, let us first look at some of the evidence, function by function.

Evidence of Function 1: Averting Risks of Dual – Market and State – Failure

As Figure 2 shows, during the post-1990 era, there has been a marked increase in activities aimed at monitoring and assessing the performance of countries, notably that of their governments, in an ever-larger number of issue areas.

For one, governments are keeping a closer check on each other through mutual monitoring and assessment of national-level compliance with international agreements, ranging from oversight of country-level progress toward the Millennium Development Goals (MDGs) and respect for human rights to control of international terrorism, curbing of greenhouse gas emissions, and tackling of excessive financial volatility. In addition, states are also subject to increased monitoring, review, and ranking by nonstate actors, including international traders and investors, rating agencies and civil society organizations.

In fact, as Keohane (2012) shows, moralism and legalism, as well as legalization, have been on the rise in the post-1990. Among the indications are the increased use of sanctions by the United Nations Security Council, the new norm of responsibility to protect, and the creation of the International Criminal Court and the Appellate Body of the World Trade Organization.

While pressure on state actors to cooperate is intensifying, nonstate actors, for their part, appear more forthcoming in revealing their preferences and demonstrating willingness to contribute to global public goods. Indicators of this willingness include the growing number of individuals and associations that engage in global advocacy, voluntary norm and standard-setting, corporate social responsibility initiatives, the creation of private foundations supporting global public policy purposes, and the volunteering of time, knowledge, and expertise. The demand for, as well as the production of, 'green,' 'safe,' or 'fair price' private goods also signals a desire to contribute (Edwards, 2011; Granville and Dine, 2013; Hale and Held, 2011).

Of course, many private-sector actors still fail to internalize the externalities of their actions such as excessive risk taking. Yet, as the follow-up to the 2008 financial crisis has once again shown, it is often hesitant regulatory behavior on the part of governments that allows this behavior to continue. State failure frequently precedes market failure, not least due to market pressure on states.

Thus, we see that the problem of free riding of states in the presence of global public goods is clearly being recognized and responded to – by state and nonstate actors. Both, state and nonstate actors fail in the presence of global public goods, and both intervene to nudge others into action. Yet, as policy tools like monitoring and review are merely tools, we also see that their increased use does not necessarily tell us anything about the direction in which policy is moving, for example, to which side the market/state balance is tipping. The policy content depends more on the openness of policymaking, the aspect reviewed next.

Evidence of Function 2: Promoting Global Fairness

Turning first to the process dimension of global fairness, the days of relatively closed, 'statist' international cooperation are clearly gone, as suggested by the foregoing discussion. This

Figure 2 Increase in indices measuring and ranking the performance of states in select issue areas. Source: Bandura, R., 2011. Inventory of Indices. Available at https://sites.google.com/site/inventoryofindices/ (accessed 06.08.14.).

change did not – or not only – happen because some international agency or global leader took a deliberate decision to encourage broader participation of nonstate actors. Rather, it has been a 'bottom-up' process (Kaldor et al., 2012). More nonstate actors became internationally engaged and connected, sought avenues of consultation with multilateral organizations, and set up their own platforms like the World Economic Forum and the World Social Forum. By now, although the democratic credentials of civil society organizations themselves still pose a challenge, most multilateral organizations have institutionalized channels of consultation with civil society (Scholte, 2010).

Like the nonstate actors, the developing countries did not sit by waiting to be granted a more effective voice in multilateral organizations by the conventional powers. They, too, created their own associations, including regional and issue-specific cooperation venues, as well as their own leadership forums like the summit meetings of the BRICS (BRICS is a forum of leading emerging economies, including Brazil, Russia, India, China, and South Africa.) – and they succeeded in influencing international agendas and negotiation outcomes (see, e.g., UNDP, 2013; De Lombaerde et al., 2012).

Yet, unlike in the case of the nonstate actors, developing countries have been granted only modest increases in their decision-making power, for example, through quota reform in the International Monetary Fund and through their participation in the Leaders' G-20. Moreover, opposite trends can also be observed. For example, venue shifting on the part of the major industrial countries has given preference to smaller, informal negotiating groups, as well as bilateralism (Skidmore, 2012; WTO, 2011).

Not surprisingly, the major multilateral negotiations today are increasingly stuttering. Just think of the Doha Round of Multilateral Trade negotiations, or the global climate change conferences in Copenhagen, Cancun, and Durban. However, within both developing and industrial countries, international cooperation in the form of cross-border policy harmonization appears to be on the rise. This is notably the case when such steps generate 'immediate' national cobenefits, as they often do in the areas of climate change mitigation and energy security (see, e.g., REN21, 2013), and when a market-based, private-good approach to meeting global concerns can be taken.

Thus, what we seem to be witnessing is a multiplication of venues and events, and with it, a growing deconcentration, as well as informalization, of decision-making on global issues. This includes the wielding of more responsibility and initiative by nonstate actors and, frequently, bypassing of the conventional organizations.

In due course, and to the extent that they will not only be happening ad hoc but form part of a deliberate strategy of vertical, as well as horizontal, subsidiarity, these trends could have important positive effects in affording different actor groups enhanced policy space. For the time being, however, they seem to be of an ad hoc, experimental and unsettled nature, and they are placing constraints on the second dimension of global fairness: the pursuit of mutually beneficial cooperation bargains.

Signs of the pursuit of positive-sum thinking and win/win strategies are barely evident. The conventional powers, notably the United States, are no longer as willing as they previously were to 'foot the bill' for international cooperation, and the new, emerging powers are not yet prepared to step into the resulting void (Ikenberry, 2008; Skidmore, 2012). Moreover, this retreat from multilateralism means more challenges remain unresolved and, in turn, fewer arguments remain for policymakers to convince electorates about the merits of international cooperation. This task is especially difficult given that in many wealthy countries the notion of 'embedded liberalism' is on the wane and inequity is rising (Galbraith, 2012; Ruggie, 1997). In fact, some analysts (e.g., Bremmer, 2012, Rachman, 2010) warn that we are heading not toward a positive-sum world but away from it.

Evidence of Function 3: Facilitating the 'Getting to the Good'

The trend toward actor pluralism is perhaps even more pronounced on the operational side of international cooperation than on its decision-making side. Most striking is the proliferation of single-issue delivery and financing mechanisms since the 1990s (Conceição, 2006; Reisen, 2010). An important driving force behind this trend has been the encouragement and facilitation of a greater role for private-sector actors in international cooperation, including through new and innovative ways of tapping private finance and the creation of incentives for private business to engage in pro-poor production efforts. Another propelling force has been the realization that some summation-type provision processes – for example, polio eradication or terrorism control – include 'weak-links' that require targeted support in order for the good to emerge (Kaul and Conceição, 2006). And a third impetus for the rise in single-issue mechanisms has, obviously, come from civil society and their strengthened international engagement.

Although these varieties of global issue management are important and perhaps contribute to a strengthened result orientation, they concern only select subcomponents of global public goods. To illustrate this point, a new drought-resistant crop may be a critical input in enhanced food security, but much more than this lone input will be required to achieve the overall goal.

Awareness of the importance of overseeing the provisioning of global public goods in a more holistic and consolidated way appears to be growing slowly (as also shown by Dubash and Florini, 2011; Elson, 2012; Kickbusch et al., 2013). The UN Secretary General has, for example, appointed a growing number of eminent personalities as his Special Representatives to issues of global concern. Yet their role is mainly one of advocacy.

Similarly, states are now appointing 'issue ambassadors,' that is, diplomats not assigned to countries but to topics like HIV/AIDS, climate change, energy, multilateral trade, or human rights, and issue-specific transnational networks of government officials have become a reality (Slaughter, 2004; Hale and Held, 2011; Reinicke, 1998). Examples are the Financial Stability Board and the International Association of Insurance Supervisors. However, national institutional arrangements that allow global issues to be addressed in a comprehensive manner are still rare, both on the legislative and the executive side of policy-making.

Thus, the provisioning of global public goods today is still a fractured process, and therefore, it should not surprise that despite countless practical–political initiatives at all levels many of these good continue to linger in a state of under-provision. They lack an anchoring agency or agent to nudge all concerned actors to go the extra mile: to jump over their narrowly conceived private or national interest hurdles and do what is required to actually get to the good. And a reason for this might be that the transnationalness of the provision path of global public goods has so far found only faint recognition.

In fact, in some cases not only is more focused global issue management absent but also attention to the global public domain as a whole, as discussed next.

Evidence of Function 4: Supporting Global Sustainability

When the 2008 financial crisis erupted, the G-20 was established as the world's premier forum for international economic cooperation. However, member states' resolve to cooperate in tackling the crisis weakened over time. Yet, when assessing the G-20's performance, one must bear in mind that what "was done in 2008–2009 was by nature exceptional and the following steps were bound to be of lower intensity" (Pisani-Ferry, 2012: p. 33).

Also, Kharas and Lombardi (2012) remind us that the G-20 is not an operational body itself. Rather it tries to help build global consensus and to provide the required political momentum to nudge others into action. In the authors' view, "the G-20 appears to be the 'best available option' for global economic governance" (p. 16).

While this might be so, the fact is that many critical global issues have not yet received the Group's full attention, despite multiplying warning calls from reports such as the one on why we must avoid a 4° global temperature rise (PIK and Climate Analytics, 2012). Similarly, the broader issue of a new, more sustainable, and inclusive growth and development paradigm, while finding considerable popular and business interest, is still lacking decisive support from world leaders, as shown by the 2012 Rio +20 conference (Khor, 2012). And even more limited issues remain unresolved, such as the continuing inconsistencies between the global intellectual property rights regime and global health (Kickbusch et al., 2013).

So again, while many initiatives are materializing, a systematic approach to managing the overall structure and functioning of the global public domain is not yet in sight. Global leadership in support of the provisioning of global public goods occurs haphazardly, mainly in response to major crises. This corroborates what we already saw in the previous point and what also earlier studies (e.g., Shah, 2012; Stone, 2008) found: the lack of a clear notion of global space.

In Sum: Relevant Initiatives Exist, but Not yet a Policy

Measures fitting the functional profile of global public policy are clearly discernible. However, they do not yet seem to be coalescing to form a recognizable, new policy strand.

While many state and nonstate actors are involved, in large numbers and at all policy-making levels, it seems that rights and responsibilities are unclear and roles blurred. No one appears fully in charge. In fact, governments can often be counted among the more reluctant actors, hesitant to restrain their own free riding attempts, as well as those of nonstate actors in the presence of global public good-type challenges.

Certainly, we live in a multiactor world, and important resources now reside in the private sector. Public–private partnering is, in many instances, essential to getting things done. Nevertheless, governments seem to be the best positioned actor group to foster the delivery of what is perhaps the most essential global public good: an institutional architecture that allows the currently messy process to take on a more organized, focused, and, thereby, effective shape. But, if we want governments to do that, we need to understand what currently limits their willingness to cooperate and how they could be persuaded to become more forthcoming facilitators of global public policy.

Section The Missing Link: A Sovereignty-Compatible Rationale for Global Public Policy will point to some of the existing impediments and propose possible next steps that might be required in order for global public policy to advance.

The Missing Link: A Sovereignty-Compatible Rationale for Global Public Policy

Reluctance to engage more actively in international cooperation exists on the part of the weaker states, as well as on the part of the major powers, and each side recriminates (Subramanian and Mattoo, 2012). One driver of this reluctance to cooperate is the noticeable lack of global fairness. For example, the perception of unfair burden sharing has been found to weaken public support for international cooperation in the more powerful, richer countries (Skidmore, 2012).

The way in which many policymakers, as well as scholars, journalists, and hence, the public at large, think and speak about international cooperation provides a clue to another – and perhaps, even more fundamental – possible impediment. International cooperation is often perceived as running counter to the core principle on which the present world order rests: noninterference by external forces into states' internal affairs, or, put differently, into their national policy-making sovereignty.

At first sight, global public policy appears to imply just that. It requires the recognition of common interests and a bridging of the foreign/domestic divide. This suggests a blending of national and external policy concerns. To achieve that, the state would need to act – at least in fields of policy interdependence among countries – as an intermediary between national and global concerns. In many instances, states are already playing this role (see, Kaul, 2006). Yet, they are often playing it reluctantly, because many perceive this role as entailing a loss or transfer of national policy-making sovereignty to international organizations and other globally engaged actors. As a result, policymakers frequently shy away from international cooperation even where it would certainly constitute the better approach to meeting national interests. Because, how sovereign are policymakers and countries when, due to a lack of international cooperation in key areas, they come under attack from forces such as financial crises, catastrophic storms or floods, terrorist actions, or new and resurgent communicable diseases that hold no respect for national borders?

In these cases, reluctance to engage in multilateral cooperation leads to a 'sovereignty paradox': The harder governments hold on to a conventional, absolute notion of sovereignty, the more they lose their policy-making capacity.

Thus, it can be conjectured that to persuade policymakers and their constituencies to break out of this paradoxical situation, it is important to define a sovereignty-compatible rationale for global public policy. This is might entail taking two main steps.

First, it must be established that, especially in policy areas involving interdependence challenges, it is rational and feasible for states to engage in effective – and to that end, fair – international cooperation. This could, for example, be done by complementing studies on the economics and politics of particular global issues, such as the Stern Review (Stern, 2007), with country-specific analyses.

Second, based on such evidence, it would be useful to forge global consensus on a notion of mutually respectful sovereignty. This notion of sovereignty would combine the pursuit of national interests with respect for the sovereignty of other states and, therefore, with respect for planetary boundaries and other global systemic balances (De Brabandere, 2013; Ţuţuianu, 2013). Such consensus would reassure countries that other nations will come with similar – positive sum-oriented – strategies to the negotiating table.

If framed in this way, sovereignty would 'allow' policymakers to engage in global public policy without being concerned about betraying – or being perceived as betraying – the national interest. It would then be clear that sovereignty as such is not in question. To the contrary, the strategies of exercising sovereignty would be adjusted to current policymaking realities, notably the challenge of interdependence, to safeguard national sovereignty.

In other words, a sovereignty-compatible rationale for global public policy would state that mutually beneficial international cooperation is the preferred strategy for responding to interdependence challenges because (1) it fosters effectiveness and maintains national policymaking capacity and (2) it shows respect for the national concerns of others, reinforcing, whenever it is applied, the norm of mutually respectful sovereignty. Importantly, this norm, if widely adopted, would protect countries against negative spill-ins from abroad.

It is perhaps not accidental that policymakers and scholars have begun noticing the absence of a systematic conceptualization of global public policy. The global challenges that figure prominently today on both the international and national agendas seem to be of a different character than the global challenges we confronted in the pre-2000 phase of globalization. The focus then was on fostering economic openness and market integration. Many governments followed the calls for greater openness, in part, because of the promise of access to new, expanded economic opportunities, and, in part, because they were nudged along by the then superpowers. Now, the focus is on constraining openness, specifically on states' reigning in of cross-border externalities in issue areas of high global risk. Moreover, under today's multipolar power relations, the adjustment burden falls on all states.

Therefore, to avoid heading toward a zero-sum world, we need to establish a sovereignty-compatible rationale for global public policy and to develop the conceptualization and operationalization of this policy strand, offering a persuasive narrative on why and how engaging in effective multilateralism can, under certain conditions, be potentially desirable and feasible.

Global South

Abstract

The global south is a complex and dynamic concept that straddles multiple social science and humanist disciplines. Emerging around 2000, it reflects the agenda of two ascending forces in those years: the antiglobalist (alterglobalist/global justice) movement and the World Social Forum, on the one hand, and an alliance of Southern states within the World Trade Organization on the other. Generally seen as an inheritor of the emancipatory thought behind the notion of the 'third world,' in the social sciences the idea of the 'global south' is also entangled with more classical academic themes such as modernity, development, and (post)colonialism.

The concept of the global south is a very recent theoretical assemblage. One of the first formal appearances of the word was in the title of a new advocacy journal, *Focus on the Global South* (http://focusweb.org/) established in 1995 by the sociologist Walden Bello in Bangkok. A quick search through academic journals shows that the term was rarely used before the year 2000, however. From then on, it was exceptionally swiftly established in politics and academia. It was adopted as a key programmatic term by emergent global justice movements and nongovernmental organizations (NGOs) that crystallized into the World Social Forum (WSF) in Porto Alegre (Brazil) in 2001, a process still ongoing through regular meetings and publications. It was also featured as a banner for a new alliance among key 'southern' states such as Brazil, Argentina, and India during trade negotiations at the 2003 World Trade Organization (WTO) meetings in Cancun, Mexico, and was the topic of a major United Nations (UN) conference in the same year. Around that time, it began to be featured in leading academic publications as diverse as *Third World Quarterly* and *Anthropological Theory*. And in 2007, its fast rise on the intellectual-political agenda culminated in it becoming the actual title of a new academic journal, *The Global South Journal* (Indiana University Press, see http://www.jstor.org/action/showPublication?journalCode=globalsouth). A Google search shows the first appearance of the term in book titles in 1999, with a continuous upward slope afterward.

Notwithstanding its obvious geographical meaning (see further below), the term has in fact a very complex and contested referent. This complexity partly explains, and is explained by, its use in very different fields. It functions within and between those fields as an intellectual magnet bringing various separate long-standing themes together in new ways. It is used among others in international relations, political science, development studies, postcolonial studies, cultural studies, anthropology, and economics. On the one hand, it serves as a synonym for the older term 'the Third World.' This is how it is mostly used in international relations, development studies, and economics, and indeed how it was largely used at the WTO in Cancun and in the UN. Global south and global north are then the present day equivalents of the First World and the Third World, the core and the (semi)periphery, the developed and the underdeveloped world. But this older state-driven and rather 'upscale' referent is crisscrossed and energized by a very different and more informal play of 'downscale' populist democratic signifiers that evoke themes of diversity, alterity, indigeneity, injustice, dispossessions, and neocoloniality. These themes are articulated by antineoliberal popular mobilizations and subaltern resistance movements and they are aimed against the contemporary mechanisms of global capitalist disempowerment. In between these populist and state-driven fields, there is an interlocking layer of educated NGO actors and practices that brings the two levels in conversation. These upscale, midscale, and downscale meanings all have their own academic representatives. Upscale and downscale fields also seem to get blurred in academic discussions, making them slightly unpredictable and exciting.

Interwoven through these fields, there is also a certain homology between the idea of 'the global south' and the older scholarly theme of postcoloniality. Here, the idea of the global south has been used to bring the histories and complexions of various ex-European postcolonies together, and to associate them with the injustices and inequalities signaled by the new cycle of subaltern political energies in the postcolonies. In the process, a new political life was given to a field that had become almost equated over the years with high-brow postmodernism, in particular in its Indian variants. But this amalgamation of the idea of the 'global south' and postcoloniality seems only to have arisen after the first two forces, the movement and the state level, had done their combined intellectual work around the notion of 'the global south.' Postcoloniality/global south has swiftly become an influential mode of writing in academia and is perhaps most obviously articulated in the work of the Portuguese public intellectual and sociologist, Boaventura de Sousa Santos. In anthropology it features, for example, in the work of Arturo Escobar and the recent writings of Jean and John Comaroff. Other important authors are the Chinese American historian Arif Dirlik, the Indian publicists Arundhati Roy and Vandana Shiva, among others.

This multiple field of meanings betrays the origin of the concept of the global south in the partial coming together of a new cycle of left wing popular mobilizations in both the south and the north under the umbrella of a broadly defined 'alterglobalist' movement ('antiglobalization movement' or 'global justice movement') as it emerged from the Seattle

anti-WTO demonstrations in 1999, on the one hand, and the politics of trade, development, and globalization at the top echelons of global governance in the early 2000s on the other. It is therefore fair to say that the notion of the 'global south' was, and still is, a 'movement' concept. It is a movement concept stemming from and feeding into movements of both high and low politics, state driven as well as populist, and is generally geared to a renewal of the Left, with intriguing linkages upward and downward, and with different sections and agendas of academia, public intellectuals, and the NGO world involved in both tiers.

To understand its rise, use, and possible meanings, one must place it in its proper historical context, and indeed in relation to the historical process to which it responds and which it is meant to challenge, that is Northern led neoliberal globalization.

The 'Third World' and Its Neoliberal Undoing

Unsurprisingly, various authors have argued that the idea of the 'global south' is the successor to the older notion of 'the third world.' More precisely, it is argued, it is the inheritor of the emancipatory impulse behind the Bandung conference and the 'Nonaligned Movement' (NAM) operating as a bloc at the United Nations. The NAM came into being at the Bandung conference in Indonesia in 1955 and was led by Sukarno (Indonesia), Zoe En Lai (China), Nehru (India), and Nasser (Egypt), shortly to be joined by Tito (Yugoslavia). It started with around 90 member states, all just recent or soon to become independent former Western, Ottoman, or Japanese colonies. The NAM was designed to keep the domestic choices of the newly independent states free from interference or intervention by the First or the Second World, which continued to monopolize the Security Council. And it tried to keep the United Nations to its promise to help 'develop' the new nations rather than being a forum for great power confrontations between East and West in the Cold War. The NAM thus was a major engine behind 'development' as a world goal.

The activism of the NAM had been preceded in Latin America by the formation of CEPAL (1948, Chile; the Economic Commission of Latin America) and was followed by the creation of the United Nations Conference on Trade and Development, the UN organization for industrial development led by the left wing Argentine economist Raul Prebisch, former director of CEPAL. The NAM was immediately confronted with the less than gentle realities of 'development' in a system that remained under control by Western capitalist states, which were demonstrably ready to use violence if their interests were threatened, for example, by nationalization: the coup against Mossadeq in Iran (1952), the Suez crisis (1956), the coup against Sukarno, the very organizer of Bandung, plus the subsequent Indonesian mass massacres (1964/5). Against this, the NAM succeeded to push through at the UN General Assembly its radical proposal for a New International Economic Order (NIEO) (1968). The NIEO entailed nothing less than a demand for far-going control by Third World states over international capital and trade flows, and a serious redistribution of technical expertise to the new nations. It was an outright claim by the Third World to a good chunk of actual power over the global system and a radicalization of the development framework. This was then one of the most memorable political markers of the rising 'New Left' in the world of the 1960s and 1970s. Intellectually it was supported by 'new' structuralist theories in development economics, 'dependency theory,' world systems theory, various new Marxisms, and a popular 'third worldism' actively endorsed by the New Left in the West too. These intellectual streams were united in their emphasis on the ways in which global linkages between cores and peripheries had historically been working against the interests of the peripheries and they led to a claim for reversing the skewed balances. After years of foot-dragging by the West, the compromise at the UN of all this was the infamous 'Brandt Report' (1981), supervised by the former socialist mayor of West Berlin and dynamic left wing Chancellor of West Germany in the early 1970s. The Brandt report endorsed the moral and political claim for a global redistribution of power. The report, however, came 10 years too late to effectively influence the way the world was evolving, and thus remained a dead letter. The 'global south' now in fact grasps back to it as the historical embodiment of broken promises.

The transformation of the capitalist world system through diplomacy between states at the UN General Assembly, then, did not happen. Instead of a 'new order,' the new nations experienced crisis and indebtedness, with the International Monetary Fund (IMF) leading 'structural adjustment.' This implied privatization of publicly owned assets, and the spread of a 'new international division of labor' through the proliferation of 'export processing zones.' The IMF had been transformed around 1980 from a Keynesian tool to manage trade imbalances into a debt collection agency for Northern capital in the indebted South and East. It began rolling over sovereign debt to private banks with public loans, in exchange for which the recipient sovereigns had to accept a substantial loss of sovereignty. It imposed debt interest payments equaling 10% of the gross domestic product (GDP) or more on its clients, as well as 'Structural Adjustment Programs,' which forced states to privatize public assets, liberalize trade, reduce subsidies and entitlements, and stabilize the currency. It led, predictably, to a massive export of capital from the periphery to the center. Africa and Latin America would thus experience lost decades in the 1980s and 1990s, with poverty multiplying, inequality going completely out of hand, a rural exodus translating into mega-urbanization without industrialization, and therefore into ghettoization, increased precariousness of life, and finally the veritable fracturing of states, in particular, in Africa. This, in the midst of an IMF-enforced national policy theater that was tightly focused on the myths, rituals, and protocols of 'globalization' and 'economic growth' (GDP) facilitated by global investment and export-driven earnings in the private economy. This did create new business classes, farmers, and entrepreneurs in the south, but earnings would consistently fail to trickle down, let alone structurally improve common life in the postcolony (until the 'rise of China' after 2000). Instead, then, of a NIEO on behalf of universal social emancipation, the 'Third World' received the 'Washington Consensus' and a neoliberal imperial hold over national politics. The goal of state politics transformed from emancipation for all to the administration of private accumulation. In the process, the NAM lost its relevance and coherence, and the 'Third World,'

once united by a desire for emancipation, liberation, and autonomy, broke down into an incoherent collection of mere 'emerging markets.'

While the Third World was collapsing, the 'Second World' of socialist people's republics cracked under very similar stresses of stagnation, indebtedness, and the swift evaporation of its rulers' popular legitimacy. It subsequently underwent not fundamentally different processes of privatization, unequalization, and immiseration, advocated under the rubric of 'democratic transition.' Democracy was also the promise with which the West would sell its undoing of 'corrupt' statist 'Third World' elites to their constituents. Following this came in the 1990s 'transparency,' 'civil society,' 'human rights,' and 'good governance.' By the late 1990s, it was realized that while these were all perfectly noble 'goods' in themselves, in this wider historical context of worldwide social polarization and declining popular sovereignty they did not by themselves bring much improvement to a quite generalized dismal situation. The emergent alterglobalist movement in the late 1990s realized that democracy and human rights, in short 'the liberal goods' produced by what Huntington had called the 'third wave of democratization,' had served more as smoke screens than as tools for mass empowerment. One can point to the Seattle demonstrations of 1999 against the WTO meetings as the moment at which globalization as the global resurrection of the royal right of property over everything else was unmasked. What was demanded was a different globalization, a globalization 'from below' rather than one for capital and Northern/Western ruling classes. This, then, was the moment at which those twin notions were publicly discovered that, together, would help shape a new global left and a new sense of universal emancipation versus mere administration: 'globalization unmasked as global neoliberalism,' and 'the global south' as its prime victim and its foremost challenger.

Antinomies of the 'Global South'

The anti-WTO protests in Seattle 1999 had been supported by an unprecedentedly wide array of organizations from various parts of the world. The groups had been crystallizing during the neoliberal 1990s, often building on older initiatives. They included Brazilian and Indian peasant organizations, urban black and left wing groups from South Africa, South African and Korean labor organizations, *afficionados* of the Zapatistas and the indigenous groups from Chiapas, whose rebellion in 1994 against the North American Free Trade Agreement had prefigured the emerging alterglobalist movement. But, happening in Seattle, they featured above all American, Canadian, and European labor union delegations protesting the offshoring of jobs, the decline of the Northern welfare state, and the dwindling of workers' influence. Newly emerging Northern left wing youth groups, some of them inspired by the Zapatistas, played a dynamic role too, as did Northern peasant and farmer groups. If the Zapatista uprising in Chiapas had been a forerunner for the Southern mobilization, the French labor and student mobilizations of 1994/95 had laid some of the complementary organizational and intellectual groundwork in the north. Northern and Southern protest had not grown independently of each other. The 'left hand' of the state in the north, including the associated Northern development organizations, had been key sponsors of peasant organizations in the South, while Southern Left authors had contributed regularly to *Le Monde Diplomatic*, the quintessential Left intellectual forum in 1990s Europe, in which Pierre Bourdieu and other Left intellectuals had become active.

In Seattle, all this came together for all to see in the form of a '*new* new Left internationalism.' This new internationalism then came fully into its own at the first WSF in Porto Alegre, 2001. This new 'Left internationalism' did not deny its historical association with the first two 'Northern' Internationals – the First International of 'the working men's association' under Marx, and the Second International of late nineteenth-century European social democracy, although they played them down somewhat – but it rejected the heritage of the Third International, controlled by Moscow. The rejection of the latter, however, remained somehow more significant than the endorsement of the former, which was under suspicion of having deep connections with the latter. The WSF rejected equality through centrally administered state-bureaucratic homogeneity, and declared diversity and the participatory democracy of human communities as its ultimate objectives. In a sense, therefore, one could say that it prioritized the heritage of the Mexican Revolution of the 1910s over the French and Russian revolutions, this time peaceful and worldwide, a revolution of the subalterns not aimed at taking power, but at rejecting all concentrated power. This was a revolution on behalf of indigeneity, ecology, communities, sodalities, villages and cities, and women, against the homogenizing militarized Leviathan of Northern capitalism embodied in WTO, IMF, World Bank, transnational capital and corporations, and the neoliberal policies of the United States and Europe – in short, against the Washington-Wall Street complex and its satellites.

Seattle and the WSF, thus, were the outcome of a longer run process of mobilization, ideological articulation, and alliance formation 'from below.' However, they did not come about without crucial inputs by NGOs, academics, political parties, and the left hand of Northern and Southern government organizations. Tellingly, many of the ideas of the WSF had already been voiced in the worldwide protest movements of the 1970s and had been institutionalized in their consequent NGO-ization in the 1980s and 1990s. Here clearly was a worldwide protest cycle coming to full fruition in a moment of global coordination and radicalization. The notion of the global south, in this context, expressed the will to create a set of intra-south alliances among movements and new knowledge positions. But it also served as a universal metaphor for the excluded and oppressed peoples of global neoliberalism in general, including those in the north, which could become aligned like in Seattle and form a global force, not necessarily only in the Southern hemisphere. Here was a tension in its references that would not anymore go away.

At exactly the same time, a not unrelated shift of governmental power to a more radical Left was happening in Latin America, with Brazil and to a lesser extent Argentina and Venezuela as the most important players. India also alternated back to the Left. As a result, the notion of the global south was now taken into the UN and in particular into the calamitous WTO meetings in Cancun 2002. There, it served as a tool for unifying the Southern positions on trade versus the north. 'The global

south,' generally pro-free trade in the 1990s, was now demanding protection against free trade, against the imposition of intellectual copyrights and the wielding of corporate and financial power. And it did so explicitly on behalf of global social justice and the popular sovereignty of its indigenous peoples, peasants, and workers, indeed of its whole cultural patrimony and ecology. The claims of the movements and the claims of states had become closely aligned. In the process, unsurprisingly, the notion of the global south became harder, more realist, more law oriented, less metaphorical and fluid, now often denoting a hard geopolitical and geocultural divide between identifiable world regions. The potential northern antineoliberal globalist connection had faded.

Here are some of the antinomies inscribed into the notion of the global south that have resulted from this shift and tension. Most social science authors who use it do so in a low key and are keenly aware that the geographical referent is problematic. For one, it is blind to the consequences of the collapse of the Soviet Union: Central Asian nations such as Tajikistan and Kyrgyzstan are among the poorest peasant countries on earth. Postsocialist countries in the Balkans such as Bulgaria and Romania, now even members of the European Union, have on some counts lower average incomes than the averages for Latin America. The Baltic countries as well as large parts of Ukraine could well be located in the Southern Cone for their income and dependency situation. Also, Pakistan, India, Vietnam, and Haiti are in the northern hemisphere, Australia and New Zealand in the southern. The whole Arabic and Islamic world remains unidentified. Most importantly, China does not figure at all in this mapping. Sao Paulo, Mexico City, and Mumbai have among their citizens some of the very wealthiest and most powerful people on earth. The inequality indices of the Latin American global south are by now roughly matched by those in Russia and China. And while it should be admitted that their social problems and social structures are not simply comparable, the same can be said about the comparison between Latin America and Africa, or Argentina and Bolivia for that matter. The 'global south' suggests a factual unity where that unity is only a claim, and it excludes those who could conceivably be included.

Geopolitically, the concept remains beholden to the conjuncture of the late 1990s, early 2000s. It entirely failed to anticipate some of the most crucial macrosocial developments of the 2000s, such as the eye-popping rise of China – which in 1999 was still confidently registered somewhere close to 'the global south' but now seems to have left the club; the crisis of capitalism in the United States and Europe; the next wave of mass contentious politics around the 'Arab Spring,' and the citizens' mobilizations against inequality and austerity in the global north. It has not anticipated the decline of Northern hegemony and the rise of East Asia. Its close focus on peasants, indigeneity, and complex natural and subaltern ecologies was indeed a new internationalist vision but it turned a blind eye toward ongoing processes of worldwide industrialization and urbanization, in fact the globalization and multiplication of the proletariat, flanked by Marxian 'reserve armies' and 'surplus populations.' These were the sorts of world processes for which the intellectual heritage of the Mexican revolution as compared to the French and the Russian revolutions could not deliver much of a compass. But they were the transformations responsible for the unprecedented rise of East Asia, the crisis of the Northern Atlantic countries since 2007, and the new waves of mass political contention. Significantly, while Brazil was the key state player in the emergence of 'the global south' around 2000, the elite of Lula's and Roussef's 'Workers' Party' has now joined China and Russia in the altogether different league of 'the BRICS' (Brazil, Russia, India, China, and South Africa), as has India, perfectly reflecting the nature of global social change in the 2000s. It also reflects the interests of Brazil's own mighty engineering sector plus agricultural export machine. But the BRICS alliance is in radical defiance of the 'global south' agenda, with the latter's concern for democracy, equality in difference, and the protection of smaller communities and knowledges overruled by straightforward capitalist geopolitics combined with brazen disregard of even Western liberal forms of democracy among its most formidable members. Also significant is that the key social policy act of the Lula years in Brazil has been the 'Bolsa Familia,' a poverty eradication program of universal social rights that, again, derives in an intellectual sense probably more from the heritage of the Northern socialist internationalisms than from the political innovations of the WSF.

Similar antinomies around the harder and 'realist' 'global south' notion have emerged in the key intellectual works of the alterglobalist movement. In David Harvey's influential work on 'the new imperialism' (2005) and 'neoliberalism' (2007), there is a continuous reminder of the mutual dependencies, intellectually and politically, of Northern and Southern anticapitalist mobilization and critique. Significantly, he emphasizes the links between the earlier 'Marxian' internationalisms, with their key symbol of the worker, and the new 'subaltern internationalism' of the WSF with its iconic embrace of indigenous people and peasants. Instead of ontological oppositions, he sees learning, social change, new times, and new alliances. He is, therefore, much better at anticipating China and the crisis of 'the West' than, for example, Boaventura de Sousa Santos. Intellectuals such as Hardt and Negri are decidedly less sympathetic to 'the worker' and the history of the European Left than Harvey is, but do explicitly include Northern subalterns and modern migrants in their alternative for 'the proletariat,' the 'multitude,' which is of course a pre-Marxian European notion. These works all indicate the tensions between the earlier movement notion of the global south and the later statist one, including the differential alliances, intellectual heritages, and social icons that are involved.

In the more intellectual circles affiliated with the movements of the global south, many embraced a 'critique of modernity' and a rejection of 'development' while endorsing ideas of 'postdevelopment,' 'multiple modernities,' 'altermodernities,' or 'postmodernities.' Here, postcolonial theory and 'global south' theorizing overlapped. In their radical versions, most of them Latin American and Indian, these ideas went together with a call for 'different epistemologies' and a recognition of 'different ontologies.' De Sousa Santos and Arturo Escobar are good examples. These ideas often hinge, again, on a radical separation of the north and the south, or in the Indian case the west and the east. Significantly, they also tend to picture the intellectual patrimony of the north as relatively homogeneous with few internal contradictions or contestations. Santos is explicit about this. Northern epistemologies and ontologies boil down to the rational actor and

are best embodied in the dominant science of neoliberalism: neoclassical economics. An Indian version of a similar argument in a celebrated book by Chakrabarty makes identical homogenizing claims in relation to European epistemologies and ontologies, here aiming against Marx rather than neoclassical economics. Paradoxically, Chakrabarty then embraces Heidegger contra Marx, as if the two German philosophers are extractions from a different soil. Santos' framework, too, rests in important respects on another European, Antonio Gramsci, but the Italian Marxist is never mentioned. The 'north,' the 'west,' or 'Europe,' in these arguments, stand for a narrow and arbitrary cut of politically dominant Anglo-Saxon outlooks presented as absolute cultural others.

Both Escobar and Santos emphasize the need to intervene on behalf of local and indigenous knowledges, ecologies, and indeed whole 'ontologies,' terms that are closely equated within this vision. Such local knowledges, ecologies, and ontologies are assumed to be driven by the desire to sustain and conserve nature and humanity, rather than to dominate and exploit. Escobar's ethnography of the Colombian South Pacific coast is a good example. Such authors argue that this could also inspire 'postdevelopment': a development process attuned to local needs and away from development as large-scale capital accumulation. As with their idea of 'the north,' such visions have a habit of homogenizing southern local cultures, skipping over internal social differentiations, erasing cultural and political contestation, and seeing internal change and discord as coming basically from the outside. The outside, similarly, becomes just that, an absolute and singular outside. The Northern NGOs and development monies that helped to install Escobar's local NGOs are apparently not part of the north. The Colombian constitution of 1991, which emphasized decentralization and the rights of indigenous populations, is not readily seen as part of a much larger wave of Northern promoted liberal constitution-making in the early 1990s but rather as an original product of the Colombian soil.

While Latin American postcolonial notions of the global south such as Escobar's often seem to invoke or advocate the end of development and modernity *tout court*, African research, in contrast, tends to emphasize the continuing popular appeal of 'the modern,' but then a modernity of local African forms, at best in conversation with but not simply derived from European examples. Jean and John Comaroff's rich work has partly been spun around this argument. James Ferguson agrees with the ongoing popularity of modernity in Subsaharan Africa, but seems more suspicious than the Comaroffs of a mere superficial copying of European global modern forms. He describes a widespread popular political critique of the absence of once promised development European style. Other work also points to a copying of modern political forms in Africa without such forms attaining the real substance; democracy, bureaucracy, or human rights are cases in point. In India, some anthropologists like Arjun Appadurai have emphasized, like the Comaroffs, 'non-Western modernities.' But this is far from a dominant position in the South Asian literature: many postcolonial Indian authors have begun rejecting modernity altogether and identifying it as another erasure of local subjectivities by colonialism, not unlike Escobar and Santos. These are, once more, antinomies within and of 'the global south.'

The newest branch on the politicointellectual tree of 'the global south' idea is the emergence of 'southern theory' or 'theory from the south.' While Santos, Escobar, and others could certainly claim that they had been doing something worthy of the name, it only emerged as an explicit epithet in the later 2000s. The notion has first been coined in the work of the Australian sociologist Raewyn Connell. The global south was here firmly reconnected with its antineoliberal and anticapitalist social movement origin, including, although still hesitantly, the origins in the first and second internationals, and was separated once more from the 'georealist' circle of meanings that it had acquired by high state politics around 2000. The global south was taken as a vital location to theorize about the injustices, dispossessions, and political dialectics of Northern dominated world capitalism as such. The work of Connell, however, is largely about 'southern' intellectuals, and is clearly a first approach with significant omissions and some mistakes of judgment. Jean and John Comaroff gave the idea a more robust and anthropological twist – including a subtle shift of meaning expressed in the change from 'southern theory' to 'theory from the south.' They thus completed the genealogical circle by suggesting that the experiences of the violently dispossessed populations of the global south form a rich and necessary vantage point for understanding the ongoing dispossessions and disenfranchisements everywhere, including in the Northern metropolises and the deindustrialized landscapes of postsocialism. For them, the north and the south, the west and the east are caught up in the same 'all embracing process' of stepped-up capitalism. One can read their text, offered as an introduction to a set of earlier South African ethnographic episodes, as a radicalization of their earlier perspectives on modernity and the postcolony, or as an ethnographic deepening of what one used to call class struggle. But now, class struggle is in the context of populations that have been made expendable rather than directly exploitable, the lumpen undersides of capitalist transformations driven by Northern as well as local capitalists, power wielders, rentiers, and profiteers. Theory from the south, in their approach, is offered, too, as a counterpoint to northern neoliberal modes of knowing that, they claim, are increasingly forced into a bleak empiricism as sociality becomes reduced to law, contracts, and administration. In the global south, they argue, one does not have the luxury to know without theory.

Global Violence Against Women

Elizabeth A Swart, University of Southern California, Los Angeles, CA, USA

Abstract

Gender-based violence exists in virtually every culture around the globe, although local manifestations are highly dependent on structural inequalities; cultural definitions of gender; and the levels of violence in the larger society. Responses to gender-based violence in the West began as criminal justice interventions but expanded in the 1990s to include a global perspective of women's human rights, as well as greater attention to the collection of internationally comparable data sets. The current discourse (2014) incorporates dialogue on the intersectionality of oppressions, rethinking the concept of agency and focusing attention on indigenous women's perspectives.

Introduction

In the 1970s, with the growth of the women's movement in the Western world, advocacy about violence against women emphasized reforming the criminal justice model so that it would be responsive to cases of intimate partner and familial violence. In the United States, that campaign culminated in the passage of the Violence Against Women Act (VAWA) in 1994, which for the first time provided federal funding for emergency women's shelters, hotlines, and other social services. The VAWA, as reauthorized in 2013, includes protections for immigrant women, LGBT populations, and Native American survivors of gender-based abuse.

In 1995, the UN Fourth World Conference on Women issued a precedent-setting articulation of women's human rights. Known as the Beijing Platform, this document is considered by many to be the clearest and most compelling argument to date, for seeing women's rights as 'human' rights. With the globalization of the women's movement have come data-collection initiatives that aim for international comparability (WHO, 2006; Johnson et al., 2008; DHS Macro, 2014), as well as ongoing refinement of the definition of global violence to women, which now includes 'cultural' forms of violence, such as female genital mutilation (FGM). The discourse on 'women's agency' in relation to global violence is increasingly understood as inseparable from community.

International Institutional Response

The effort to address global violence against women is inextricably linked to the globalization of the women's movement. In 1947, the establishment of the United Nations' Commission on the Status of Women 'was among the most significant early developments' in the globalization of women's struggle for rights and equality. The Commission's mission was to 'raise the status of women, irrespective of nationality, race, language or religion' and to create "equality with men in all fields of human enterprise, and to eliminate all discrimination against women in the provision of statutory law, in legal maxims or rules, or in interpretations of customary law" (Penn and Nardos, 2003). These goals were, however, not specifically equated with the "need to eliminate sexual and physical violence against women and girls" (Penn and Nardos, 2003: p. 3). Nevertheless, the Commission was responsible for shaping the language of the 1948 Universal Declaration of Human Rights so that gender-insensitive language was removed and the document was tailored to affirm the inherent equality of women and men. Progress continued in 1952 when the UN General Assembly adopted the Convention of the Political Rights of Women (1954), which affirmed the inherent entitlement of women around the globe to "vote in any election, run for any political office, exercise any public function, and hold any public position that a man might hold" (Penn and Nardos, 2003). The Commission also began a partnership with UNESCO to develop equal access educational programs. And, although inequality in education is an ongoing problem in the twenty-first century, the beginning of consciousness about the disparity between girls' and boys' educations began with the Commission's early work.

From 1955 to 1962, the United Nations adopted two measures related to marriage, which were intended to reduce violence to women that was a consequence of marriage. The first was the Convention on the Nationality of Married Women (UN, 1958; Penn and Nardos, 2003), which was intended to secure nationality rights for women that is independent of the nationality of their spouses. The second measure related to the consent to marriage and minimum age for marriage (UN, 1964; Penn and Nardos, 2003), the purpose of which is to reduce the forced marriage of very young girls. The Convention, however, was weak, requiring premarital consent by both parties but leaving the minimum age of marriage to national governments.

The UN declared that 1975 would be known as International Women's Year and that the following 10 years would be the Decade of Women. During this fertile period for the confrontation of global violence against women, 'cultural' practices, such as FGM, were redefined as types of gender-based violence that constituted violations of women's human rights. The definition of violence continued to expand, incorporating structural and cultural concerns as well as health and survival-related issues. The Commission on the Status of Women, as well as General Assembly and the UN Economic and Social Council, began to focus on issues of poverty and structural inequality (Penn and Nardos, 2003). The first global conference on women's issues in Mexico City in June 1975 articulated

the World Plan of Action for the Implementation of the Objectives of International Women's Year, which consisted of three main objectives: promoting gender equality; facilitating the integration of women into all development efforts; and strengthening the contribution of women to the global movement for world peace (Penn and Nardos, 2003: p. 6). In 1979, the landmark Convention of the Elimination of all Forms of Discrimination against Women (CEDAW) was adopted by the General Assembly. Since its adoption, more than 150 nations have agreed to be bound by its provisions, although many countries have ratified the Convention without passing national implementing legislation. The Convention establishes an international bill of rights for women and mandates the establishment of a Committee on the Elimination of all Forms of Discrimination against Women, whose job it is to see that the provisions of the Convention are observed.

The International Year of the Woman was followed by global conferences on women in Copenhagen in 1980 and in Nairobi in 1985. Both gatherings brought nongovernmental organizations into prominence and influence. But it was the Nairobi conference, in particular, which cut across traditional lines of race, class, and culture to form alliances and coalitions among women from the Global North and South. A document entitled the 'Nairobi Forward-Looking Strategies for the Advancement of Women' expressed an increased urgency in the need to address cultural issues, such as FGM, as human rights issues. Because of the strength of this platform, CEDAW rectified the omission of gender-based violence from its own Convention in 1992 and categorized gender-based violence for the first time as a kind of discrimination under CEDAW. In 1993, building on the wave of grassroots human rights activism that had culminated in the Vienna Conference on Human Rights in June of that year, the UN General Assembly passed the Declaration on the Elimination of Violence Against Women, the "first international human rights instrument designed exclusively to deal with violence against women" (Penn and Nardos, 2003).

In September 1995, the United Nations held the Fourth World Conference on Women in Beijing, China. It was the largest UN conference to date, significant not only for the number of nations represented but also for the largest-ever representation of nongovernmental organizations. The Platform for Action which emerged from that conference is "among the most comprehensive human rights documents ever articulated on behalf of the world's women" (Penn and Nardos, 2003: p. 11). It established a list of 12 'priority action' areas including the persistent and increasing burden of poverty on women; inequalities in and unequal access to education and training; inequalities in and unequal access to health care; violence against women; effects of armed conflict on women; inequality in economic structures and policies and resources; inequality between women and men in sharing power and decision-making at all levels; insufficient methods to promote the advancement of women; lack of respect for and protection of women's human rights; stereotyping of women in the media and unequal access to media and communication systems; gender inequalities in the management of natural resources and in safeguarding the environment; persistent discrimination against and violation of the rights of the girl child (UN Women, 1995; Penn and Nardos, 2003: p. 12). The Beijing Platform is appropriately lauded as a landmark for women's human rights and much progress has been made in achieving the platform's goals. Although an increasing number of advocates and organizations recognized that legal and political measures were insufficient to confront the magnitude of global violence against women, new definitions were elusive.

Beyond Legal Interventions

By the turn of the twenty-first century, the discourse had turned from political definitions to ones rooted in situated understandings of social inequalities. In many parts of the world, women and girls have no access to legal mechanisms that can aid them, regardless of the lofty ideals that are codified by national and international assemblies. Violence between intimate partners began to be viewed as inseparable from "the violence of poverty, hunger, social exclusion, and humiliation" (Merry, 2009) and as

> … an umbrella term for a wide range of violations from rape during wartime, to sexual abuse in prisons, to insults and name-calling within marriages. Although the early movement against gender violence in the USA and internationally centered on rape and battering in intimate relationship international, activists continue to expand the scope of violence against women, to include cultural practices such as genital-cutting, illegal acts such as dowry deaths, the trafficking of women as sex workers, the effects of internal wars such as displaced people and the vulnerability to violence experienced by migrants in the context of contemporary globalization.
>
> Merry, 2009: p. 3

Indeed, understanding the intersectionality of gender with other forms of oppression locates violence not only in the gendered identities of the parties, but also in relation to cultural definitions and gender norms. Issues such as education and labor have become crucial in analyses of both definition and intervention. The World Bank reports that "two thirds of the 960 million illiterate people in the world are women and, of the 130 million children who received no primary education in 1990, 81 million were girls" (Penn and Nardos, 2003: p. 25). Such inequalities increase the likelihood that women and girls will experience gender-based violence through early pregnancy, forced marriage, sexual harassment, sexual violence, and early death in child-bearing (Penn and Nardos, 2003).

Similarly, women and girls work more daily hours than men but own very little of the world's wealth – performing nearly two-thirds of the work hours, receiving one-tenth of the world's income, and owning less than one-hundredth of the world's property (Frankenhaeuser et al., 1991). Women's unpaid workload and the increasing number of households headed by poor single women have resulted in more women and girls seeking employment outside the home, as well as in women migrating from rural to urban areas for jobs; with both trends exposing women to risk of gender-based violence. According to the UN's Special Rapporteur on Violence against Women, economically disadvantaged women are more vulnerable to sexual exploitation, harassment, and slavery than other women (Penn and Nardos, 2003: p. 25). Globalization, migration, and urbanization have created a market for women

in global sweatshops, which have created black holes of lawlessness and impunity where gender-based violence can flourish. The maquiladora factories along the US–Mexican border, particularly in Ciudad de Juarez, are the sites of hundreds of unsolved 'femicides' since 1993 (Segura and Zavella, 2007; Eisenstein, 2009).

Such black holes have left women and girls vulnerable to trafficking for sexual exploitation, the fastest growing criminal industry in the world. At least 20.9 million adults are bought and sold worldwide into commercial sex slavery and forced labor annually, as well as about 2 million children (ILO, 2012; UN, 2012). Women and girls make up about 98% of victims exploited for sexual purposes. Human trafficking of US citizens within the UN is also a growing business (UN, 2012). Experts estimate that at least 244 000 American children and youth – most of them very young girls – are trafficked within the United States each year for sexual exploitation. The average age of recruitment of girls into forced prostitution is 12–14 years (Estes and Weiner, 2001).

At the time of this writing (2014), the socio-cultural definition of gender-based violence has become instrumental in both grassroots and national campaigns (Bahun-Radunovic and Rajan, 2008; Merry, 2009), although efforts to reform legal and criminal justice systems continue (Bond and Phillips, 2008; Bahun-Radunovic and Rajan, 2008).

Types of Global Violence against Women

Domestic and Intimate Partner Violence

Violence against women by their male partners sustains patriarchal family structures, creates a hierarchy of male domination, and maintains women in a position of subordination (Seager, 2009: p. 28). Domestic or intimate partner violence is the most ubiquitous form of violence against women around the world. There "is virtually no place where it is not a significant problem … and women of no race, class or age are exempt from its reach" (Seager, 2009: p. 28). Although prevalence rates are difficult to compare because of definitional and measurement issues, a UN global review reports that 35% of women worldwide have experienced either physical and/or sexual intimate partner violence or non-partner sexual violence. Some national violence studies show that up to 70% of women have experienced physical and/or sexual violence in their lifetime from an intimate partner (UN Women, 2012). In Australia, Canada, Israel, South Africa, and the United States, intimate partner violence accounts for between 40 and 70% of female murder victims (Krug, 2002). Although advocates continue the struggle to expose and eradicate intimate partner violence, in many countries it is still condoned by the state as a 'private matter' (Seager, 2009: p 28).

Sexual Violence

Women around the world experience rape, often by men they know. In many countries, advocates have succeeded in changing the definition of rape from nonconsensual sex to a "violent act intended to assert male domination and control" (Seager, 2009: p. 58). Nevertheless, in most if not all countries, rape carries a social stigma that reduces reporting. Experts estimate that the actual incidence of rape may be 50 times greater than the number actually reported. In the US, up to 700 000 rapes are estimated to occur each year (Seager, 2009: p. 58). In South Africa, a woman is raped every 83 seconds (Seager, 2009: p. 58.) Around the world, the problem of institutional rape is on the rise, as is the rape of women in prisons, jails, border-crossings, and refugee camps (Segura and Zavella, 2007; Leatherman, 2011).

The subject of rape as a weapon of war drew international attention through the testimonies of female survivors of genocide in Bosnia–Herzegovina, as well as through the subsequent establishment of the International Crimes Tribunal for Yugoslavia in 1993. The Tribunal "created new categories of crime that were themselves gendered" (Giles and Hyndman, 2004) and for the first time in history, rape was prosecuted as a weapon of war and a crime against humanity (Giles and Hyndman, 2004). Women told stories of rape as a genocidal tool; of being imprisoned in rape camps; of being tattooed and marked with enemy insignia; and of being forced to bear their captors' children. Radhika Coomaraswamy commented on these atrocities by noting that "to rape women with impunity and to mark their bodies with the symbols of the other side is to assert domination and to symbolically assault ethnic identity in its most protected space" (Coomaraswamy, 1999: p. 10). Mass rape is also an efficient means of displacing surviving postconflict populations, whose families and communities are torn apart by shame, horror, and trauma (Coomaraswamy, 1999; Giles and Hyndman, 2004).

According to Leatherman (2011), sexual violence as a weapon of war has expanded to epidemic proportions. In 2006, the UN reported 27 000 sexual assaults during conflicts in Congo's South Kivu province alone (Leatherman, 2011: p. 120). Conflict-related sexual violence crosses thresholds related to type of sexual violence; target of sexual violence; extreme coercion of the sexual subject; and the loss of neutrality or safe space for the victims of sexual predation. The type of sexual violence is often public gang rape, perpetrated in schools, marketplaces, churches or other locations not normally conflict-related. Violated bodies are often left on display. Rape may also be performed with material objects – bottles, guns, spears – or victims may be knowingly raped by individuals carrying HIV/AIDS, with the intention of infecting the victim. The range of targets of sexual violence continues to expand – women in their 80s and children as young as 2 years old are currently (2014) raped with impunity in the Congo (Leatherman, 2011). Extreme coercion – forcing an unwilling perpetrator to commit acts of sexual violence, such as forced incest – imbues a sense of powerlessness and loss of agency among victim populations. Conflict-related sexual violence acknowledges no neutral zones or white flags and is perpetrated in churches, sanctuaries, refugee camps, homes, and other supposedly safe places. Such egregious sexual violence destroys the fabric of families; creates lasting wounds, such as PTSD and mental health disorders; neutralizes and disempowers communities that might once have considered fighting back; and normalizes sexual violence in postconflict society.

In 2000, the UN Security Council unanimously adopted Resolution 1325 (S/Res/1325), which aims to protect women and girls from violence, including rape as a weapon of war. It also advocates for the inclusion of women in conflict

resolution programs. The Inter-Agency Task Force on Women, Peace and Security facilitates collaboration on this Resolution among more than 20 UN agencies, as well as *between* UN entities and nongovernment organizations working on the ground in specific conflict areas (Olonisalom et al., 2011).

Traditional and Cultural Practices

FGM is a "cultural practice involving the removal of various parts of the genitalia of girls and young women" (Penn and Nardos, 2003: p. 89). It is performed in at least 27 African nations and in several countries in Asia and the Middle East (Yoder et al., 2013), as well as by immigrant and refugee communities in Western nations. Experts cite Sudan, Ethiopia, Mali, Egypt, Sierra Leone, and India as countries with the highest rates of FGM (Penn and Nardos, 2003: p. 88). Although the practice has come under fierce criticism by medical and mental health professionals around the world, the World Health Organization (WHO) estimates that in 1994, at least 114 million girls and women endured some type of FGM (Penn and Nardos, 2003: p. 89). FGM procedures, usually performed without anesthesia and in unsanitary conditions, can result in complications such as shock, hemorrhaging, urinary retention and infection, fever, painful intercourse, complications during childbirth, and death. There are three types of FGM. The first, 'clitorectomy' (sunna) involves partial or complete removal of the clitoris. 'Excision' involves the removal of the clitoris and the labia minora. 'Infibulation,' the most dangerous and most common form of FGM, involves the removal of the clitoris, the labia minora, as well as the inner surface of the labia majora, followed by the sewing together of the vulva so that a small opening for urine and menstrual blood remains. A process known as 'defibulation' – a surgical reopening – must sometimes be performed before sexual intercourse is possible. Scar tissue created by infibulation often inhibits childbirth or makes it extremely painful.

In countries where FGM is pervasive, women sometimes report submitting to it (for themselves or for their daughters) as a means of community acceptance – a necessary prerequisite for marriage and employment. Uncut girls are often considered ugly, unclean, promiscuous, and unmarriageable. For this reason, women's empowerment within communities and education about health issues must be addressed if FGM is to be eradicated. In many countries, indigenous women are speaking out against the procedure. In Kenya, for example, advocates have created alternative rites of passage for girls, which include a community-based initiation to womanhood that does not include genital cutting (Chege et al., 2001).

Dowry murder (bride-burning or dowry death) is "the murder of a woman who is set on fire by her husband or in-laws for the purpose of keeping the dowry that the woman brought into the marriage. By burning his wife, the husband can remarry and obtain another dowry" (Penn and Nardos, 2003: p. 97). Dowry murder, particularly common in India but also occurring in other parts of Asia and the Middle-East, is most commonly done by pouring kerosene on a woman and setting her on fire. Because many homes have kerosene-fueled stoves, those who commit the murder may attribute the death to a cooking accident (Penn and Nardos, 2003: p. 97). Studies on rate and prevalence of dowry murder in India show that it persists in all levels of society, despite the passage of the Dowry Prohibition Act in 1961. Families in lower socio-economic levels may use it as a way to escape subsistence poverty. Educated classes may use it as a method of retaining their status (Penn and Nardos, 2003: p. 99). Ironically, because the Dowry Prohibition Act criminalizes both dowry-giving and receiving, it discourages reporting of the dowry-related crime. Experts estimate that 5000 women per year in India may be victims of dowry-related murder. However, it is important to understand that violence in India, as in many developing countries, is often viewed by the West "in its most extreme incarnation" (Narayan, 1997: p. 101). It is helpful to remember that "the level of reported homicide by a partner in proportion to the country's population is, in fact, similar in India as in the United States …" where spousal murders are related not to dowry but to gun violence (Narayan, 1997: p. 99).

Honor killing, an ancient practice in which men kill female relatives in the name of family honor, are also on the rise in the twenty-first century. These killings occur in societies where women are not only considered the property of male relatives but also the standard bearers of male familial honor. Although exact numbers are difficult to obtain, experts estimate that in 1997 in one province of Pakistan alone, 300 women were killed to protect or avenge family honor. In Yemen, approximately 400 honor killings took place in 1997, and 52 honor killings in Egypt during the same year (Penn and Nardos, 2003; Bahun-Radunovic and Rajan, 2008). Women are killed for refusing arranged marriages; for being victims of rape; for wearing clothes male relatives deem inappropriate; or for adhering to Western standards of behavior (Penn and Nardos, 2003; Patel and Gadit, 2008). Unfortunately, honor killings are rapidly spreading to the West, with the increase in refugee and immigrant populations from countries where the tradition is entrenched.

Measuring Gender-Based Violence

The past three decades have shown increasing refinement of methods for collecting data on gender-based violence. The first population study of gender-based crimes among the general population was carried out in the late 1960s in the United States. These victimization surveys interviewed large samples of adults, asking about their perceptions and experience of the crime in the 12 months prior to the interview (Johnson et al., 2008: p. 11). This methodology became increasingly popular in the 1970s as a tool for assessing the level of crime in society (Johnson et al., 2008) and was further refined in other Western developed nations. Researchers considered these data important complements to official police data because many crimes – particularly rape and domestic violence – are never reported to the police (Johnson et al., 2008). But although these data provided information on crime from the victims' perspective, it became increasingly clear that they were not adequately measuring gender-based crimes. Factors included lack of sensitivity in wording of questions; lack of special training for interviewers; lack of safety supports for women interviewees who might be in danger for disclosure; the traumatization caused by the reporting; and the undercounting of women's experiences of lifetime or long-term violence. Such critiques led

to the redesign of the US-based National Crime Victimization Survey (NCVS) in 1992 to improve and expand screening questions, which increased prevalence rates.

Statistics Canada was the first agency to take on a major revamping of the methodology of measuring women's victimization. In 1993, "a survey dedicated to exploring a wide range of women's experiences of violent victimization was developed and implemented, using the basic crime victimization survey methodology" but with female interviewers who were specially trained and the referral of respondents to community agencies and supports for interviewers (Johnson, 1996, 1998). Since then, similar surveys in the US, Australia, New Zealand, Finland, and Sweden have been successfully carried out.

Population-based surveys of representative samples of women are now generally recognized as the "most reliable method of acquiring statistically reliable estimates of the nature and extent of violence against women. At least 70 countries have conducted population surveys on violence against women but, although there are commonalities among the surveys, there are enough important differences to prevent reliable country-to-country comparison of results" (Johnson et al., 2008: p. 14). Those problems include the definition of violence; the specific wording of questions; reference periods (previous year or adult lifetime); and sampling methods.

Despite differences in definition and cultural manifestation of gender-based violence, there exist several exemplary efforts to measure gender-based violence internationally. In 2005, the World Health Organization (WHO) issued a report on violence to women by intimate partners. It was based on 24 000 interviews with women in 10 countries (Bangladesh, Brazil, Peru, Tanzania, Ethiopia, Thailand, Japan, Samoa, Namibia, and Serbia/Montenegro) (WHO, 2006). The study found important variations among nations, as well as among rural and urban populations within nations. Finding showed that between 15 and 71% of women who had ever been in an intimate relationship had experienced physical or sexual assault during their lifetime (WHO, 2006; Merry, 2009).

The Demographic and Health Surveys (DHS) are household surveys sponsored by Macro International and the US Agency on International Development (DHS Macro, 2014), which focus on health-related practices and behaviors in 90 developing countries. DHS country surveys contain a Domestic Violence Module which collects representative data on lifetime experience of intimate partner violence. DHS surveys use large nationally representative samples, as well as a standardized questionnaire and a methodology to ensure comparisons over time and among countries. The module includes nine questions related to acts of physical and sexual violence, as well as a series of questions describing psychologically controlling or abusive behaviors. Comparability problems remain, however, because some countries opt out of the domestic violence module or reduce it to a single prevalence-gathering question (Johnson et al., 2008).

The International Violence Against Women Survey is an important data collection method which "incorporates a standardized methodology and has as a primary focus the strengthening of legal measures and improving criminal justice responses to violence" (Johnson et al., 2008: p. 15). Analysis of survey results from nine countries provide information not only on women's experiences but also on how the criminal justice system responds and how civil society may effectively intervene (Johnson et al., 2008: p. 167).

Rethinking Agency

When the Beijing Platform was still hot off the press, indigenous women pointed out that the platform was flawed due to its overemphasis on gender discrimination and on an individual rights-based philosophy (UN Women, 1995; FIMI, 2006). Before the conference adjourned, more than 100 indigenous women from 26 countries had written a declaration outlining their critique of the Platform's theoretical viewpoint (UN Women, 1995). For indigenous women, human rights violations "are based not only on gender but on the interplay of gender" with other aspects of identity (Cunningham, 2006; FIMI, 2006: p. 10). Issues omitted in the Beijing Platform include the dispossession of territories, pollution of water, forced relocations, and other activities which, although not gender-based in their intent, have a "disproportionate effect on women" (FIMI, 2006: p. 13). Indigenous women call for an integrated analysis of violence against women that "recognizes both the near-universality of violence against women and the specificity of violence perpetrated on the basis of distinct but overlapping identities" (FIMI, 2006: p. 10). They point out that "for indigenous women, the systematic violation of their collective rights as indigenous people is the single greatest risk factor for gender-based violence – including violence perpetrated within their communities" (FIMI, 2006: p. 7).

The current discourse on global violence against women challenges scholars in the Global North *and* South to rethink agency as it relates to gender-based violence and to women's alternative ways of "being and seeing in the face of violence" (Campbell and Mannell, forthcoming). Scholars hope to 'push the boundaries of how we conceptualize agency' and to break down the neoliberal assumption that encourages women to think that leaving situations of violence is the only appropriate course of action. Current discourse pays particular attention to situations of extreme poverty, armed conflict, and migration as they challenge an individualistic-behavioral approach to gender-based violence (Campbell and Mannell, forthcoming). It also acknowledges the need to actively engage men on all levels of violence prevention and cessation (Kimball et al., 2013). Seeking global cooperative strategies capable of adapting to localized contexts (Bahun-Radunovic and Rajan, 2008) advances the struggle to end global violence against women.

Abstract

Globalization describes how nations, peoples, and economies are becoming increasingly interconnected and interdependent. Globalization has contributed to health improvements through diffusion of new health knowledge, low-cost health technologies, and human rights. Economic globalization based upon a neoliberal model of liberalized trade and investment and minimal government regulation, however, has brought many health risks. This article outlines the health risks of neoliberal globalization from structural adjustment of the 1980s, through economic financialization of the 1990s and the 2000s, to the financial crisis and global recession of 2008 and subsequent 'austerity agenda' of state retrenchment. It concludes with a discussion of high-level public policies that would ensure that globalization works for 'health for all'.

Introduction

Globalization is a relatively new term, first appearing in the 1970s and quickly supplanting earlier concepts sharing roughly similar terrain (internationalization, postcolonialism, new international economic order). Broadly defined, globalization describes how nations, businesses, and people worldwide are becoming more connected and interdependent through increased economic integration and communication exchange, cultural diffusion, and travel. Lee (2002) further considers globalization to be effecting change in spatial, temporal, and cognitive dimensions: social activities increasingly transcend borders and occur more rapidly, as do peoples' understanding of global events and their place in the world. By such an account, globalization is not a new phenomenon; rather, apart from small and geographically isolated settlements, this push, prod, and sharing against 'borders' has characterized much of the history of human societies. At base, it is driven by economic and political expansion, whether by trade or conquest.

Some historians date the 'modern' era of (Western) globalization with European colonial expansion and the Westphalia formation of nation states in the late seventeenth century. Mercantilism dominated globalization's policies and practices over the next two centuries, as governments supported their local merchant class in competition for an expanding global trade facilitated by technological advances in maritime navigation. A series of late nineteenth-century economic recessions, rising social inequalities, staggering inflation, and nationalist protectionism became the fertile ground from which the Great War emerged, which devastation and lessons failed to find a sufficiently firm political foothold to avoid a recurrence in the Second World War. This foothold became more secure in the 30 years following the Second World War, which saw a new pattern in globalization emerge with the creation of stronger multilateral governance bodies. The United Nations (UN) replaced the League of Nations. The International Monetary Fund (IMF) was created to maintain macroeconomic stability and avoid the recessionary crises underpinning both world wars. The World Bank (WB) was founded to finance reconstruction of war-torn Europe (and later, developing country economies and social infrastructure). The General Agreement on Tariffs and Trade provided a negotiating platform intended to interconnect national economies (at that time, of the high-income developed countries only) in mutually beneficial ways, with the expectation that this would also provide economic disincentives to future war.

Contemporary Globalization

A new 'contemporary' globalization began to emerge in the 1970s. More economic recessions, two oil price shocks, profligate international bank lending, an end to fixed currency exchange rates, and a 'stagflation' leading to sharp interest rate spikes in the world's (then) major economies combined to create a developing world debt crisis. This crisis provided an opportunity for neoliberal economic theories first advanced by Friedrich Hayek in the 1920s to become policy practice, in the form of structural adjustment programs imposed largely on the heavily foreign indebted countries of Africa and Latin America, which needed financial assistance from the IMF and WB to avoid government default and bankruptcy. The key elements of these programs, later codified as the Washington Consensus, are well known and included such requirements as:

- privatization of state assets to generate revenue,
- deregulation of economic markets to promote private sector growth,
- lower corporate and individual taxes to attract foreign direct investment,
- reduced government spending and increased cost recovery (user pay for public services), and
- increased trade and financial liberalization.

These policy prescriptions were intended to increase economic growth and the ability of governments both to service their foreign debt obligations and to reduce their debt burden. Evidence of their effectiveness in doing so is mixed, with other regions of the world not adopting these policies (notably Southeast (SE) Asian countries) performing much better over this period (Chang, 2005). The policies also resulted in a number of health-negative impacts, first documented with respect to children's health in the landmark United Nations International Children Emergency Fund publication, *Adjustment with a Human Face* (Cornia et al., 1987). Subsequent studies similarly found singularly negative health impacts of

structural adjustment programs, attributed to user fees that created barriers to health and education services, labor market adjustments from trade liberalization that led to unemployment or insecure informal work, and tax reductions and the loss of tariffs revenues that reduced government health and social protection spending (Breman and Shelton, 2001). But even as evidence and argument over the economic and health impacts of structural adjustment continued, the neoliberal policy context shaping contemporary globalization became firmly embedded.

Globalization's Positive Health

Even as this neoliberal model of global market integration strengthened its grip on countries' economic policies, civil society movements, the foreign aid arms of governments, and several UN agencies were emphasizing the social dimensions of global health development. Key innovations at this time included the 'child health revolution' of the 1980s, with its emphasis on low-cost health interventions: GOBI (Growth monitoring, Oral rehydration, Breastfeeding, Immunization), later followed by the triple FFF (Family planning, Female education, and Food supplementation). Some have argued that much of the improvement in global health during the last half of the twentieth century arose not from economic growth in developing countries, but from health technologies and knowledge transfers between wealthier (developed) and poorer (developing) countries (Deaton, 2003): one indication of globalization's health beneficence.

Ratification by most of the world's countries of international human rights conventions is seen as another health-positive facet of contemporary globalization. Several of these conventions make specific reference to the right to health, and most others deal with rights associated with access to social determinants of health. Though sometimes critiqued for a perceived Western bias (emphasizing individual rather than collective rights) and for their lack of enforcement (apart from 'naming and shaming' states that fail to fulfill their obligations under these treaties), international human rights have become a set of global tools used in the struggle for better health throughout much of the world (Chapman, 2002). A global diffusion of concerns for gender equity has also been attributed to globalization, from increased funding to improve conditions for maternal/child health, to new employment opportunities in export-oriented industries allowing women to earn income outside patriarchal social structures. That the poor working conditions in these outsourced factories have become a focus of international and civil society activism attests to another distinguishing quality of contemporary globalization: the breadth and reach of digital communication technologies. These technologies enable not only the more exploitative elements of open markets but also the platforms for oppositional civil society mobilizations.

The past 15 years have also seen global attention to health rise considerably. Health concerns directly informed three of the UN Millennium Development Goals, have been central in bilateral and multilateral development aid policies, and have led to the creation of over 100 global public–private partnerships for health. International financing for health followed suit, increasing substantially over this period, partly on the accumulating evidence that health should be considered an investment in economic growth, rather than a cost (World Bank, 1993; CMH, 2001).

Globalization's Negative Health

The emphasis on health as an investment relates to one of the more contentious positive health claims made for globalization: that of the contribution of liberalized markets to economic growth. This argument holds that trade and investment liberalization improves growth, which generates wealth that reduces poverty. Poverty reduction, in turn, improves health (poverty being the single greatest risk condition for disease), creating more productive and skilled workers, which spur the economy to even greater growth and more trickle-down health. It is by interrogating the links in this 'virtuous circle,' however, that globalization's health risks begin to emerge.

Most econometric studies do find that trade liberalization is associated with better growth, but this positive relationship is neither automatic nor always observed (Thorbecke and Nissanke, 2006). There also remains doubt about the direction of causality in these studies: does openness lead to growth, or does growth give rise to openness? Many development economists are critical of the assumption that liberalization is inevitably a 'global public good' for the economic growth it is presumed to engender. Some argue that trade liberalization rules are 'kicking away the ladder' of development policies successfully used by high-income countries in the past, and by middle-income SE Asian economies in the two decades prior to the birth of the World Trade Organization (WTO) in 1995 (Chang, 2005). Others point to evidence that trade and investment liberalization disproportionately benefits larger, wealthier nations with greater factor endowments and the political strength to set the terms of liberalization rules in their favor (Birdsall, 2006). One study of four different scenarios of a completed 'Doha Development Round' of WTO negotiations (so named as it was intended to give more attention to the economic interests of developing countries) showed net income gains for wealthy countries but net income losses for the world's poorest countries (Polaski, 2006). While the number of people living in extreme poverty (US \$1.25 day^{-1}) has decreased since liberalized trade began its acceleration in the 1980s, the 'rising tide' of global economic growth has not lifted people very far with poverty at the US \$2.50 day^{-1} level increasing by almost the same number (Chen and Ravallion, 2008). Expanding external trade has not been a powerful force for poverty reduction in developing countries.

There are three other ways in which trade liberalization and global market integration poses specific health risks: spread of disease, loss of government policy space and capacity, and increased labor market insecurity.

Spread of Disease

Infectious diseases such as the plague, smallpox, and cholera have long followed trade and military routes; it was a freighter's dumping of infected bilge waters that caused the Latin American cholera pandemic of the 1990s, and the deployment of UN Nepalese peace keepers that introduced cholera into Haiti in 2010. Trade has also been responsible for the movements of

insect or animal species destructive to natural resources essential for health (food, water, and biomass). Modern transportation allows such pathogens and pests to spread faster and farther, with the severe acute respiratory syndrome outbreak in the early 2000s shaking public health systems out of their recent complacency. New International Health Regulations monitored by the World Health Organization (WHO) followed quickly, as did ongoing 'pandemic preparedness' within and between countries and the 'securitization' of health within global governance structures (the WHO and the UN), wherein pandemic disease is viewed as a risk to national and international security (OUNHCHR, 2000). The global trade in fake medicines alongside the misuse of antibiotics in many countries, especially those that lack well-regulated public health systems, is heightening concern over the spread of multiple or extremely drug-resistant infections.

While increased research and policy attention is being paid to the globalization of infectious diseases, chronic non-communicable diseases (NCDs) such as cancer, cardiovascular disease, and diabetes have been steadily growing in prevalence and now account for the largest proportion of the global burden of disease, outpacing infectious diseases in all developing countries except for those in sub-Saharan Africa. The rise in NCDs, particularly problematic in many low- and middle-income countries still coping with infectious epidemics, is partly attributable to international trade and investment policies that are globalizing 'Western' lifestyles, including increased consumption of unhealthy products. The nutrition transition in many of these countries toward a low-nutrient, high-energy diet is occurring much faster and at earlier stages of development than it did in high-income countries (Popkin, 2009). Increased trade in tobacco and alcohol products, in turn, is associated with higher levels of consumption and health-related problems (Labonté et al., 2011), at the same time that trade and investment treaties are being used by transnational companies (or governments on their behalf) to challenge public health restrictions on advertising, points of sale, taxation, and other measures now widely accepted as essential tools in health promotion.

Loss of Government Policy Space and Capacity

Another aspect of trade and investment liberalization with indirect health outcome is the loss of governments' 'policy space' and 'policy capacity.' 'Policy space' describes "the freedom, scope, and mechanisms that governments have to choose, design and implement public policies to fulfill their aims" (Koivusalo et al., 2009: p. 105). Policy capacity refers to the fiscal ability of states to enact those policies or regulations, which depends upon their ability to capture sufficient revenue through taxation for this purpose. The increasing 'behind-the-border' reach of an ever larger number of multilateral, regional, and bilateral trade and investment treaties is shrinking policy space by prohibiting a range of domestic regulatory options that could be used to promote more equitable population health outcomes. Although governments retain substantial policy flexibilities within existing trade treaties, these flexibilities continue to be eroded through ongoing negotiations, notably the shift to bilateral and regional treaty negotiations, which are often 'WTO+,' limiting policy space to a much greater extent than current WTO rules. Of particular concern is the proliferation of investor state dispute settlement provisions in bilateral and regional treaties, which allow corporations to sue governments for regulations that result in expropriation of their investments, with expropriation often defined in very broad terms. Anticipating the cost of such disputes can lead governments to choose not to exercise the health flexibilities that might still exist within these treaties: a 'regulatory chill.'

Policy capacity, in turn, can be affected by liberalization's requirements for progressive reductions in tariffs. Many low- and middle-income countries rely much more upon tariffs for their tax revenue than do high-income nations. These tariff rates have come under intense trade negotiation pressures from high-income countries to be 'locked in' and rapidly reduced. In theory, governments should be able to shift their tax base from tariffs to sales or income taxes, assuming their economies grow with increased liberalization. In reality, most low- and middle-income countries subject to tariff reductions under structural adjustment loans from the IMF and WB were unable to do so (Baunsgaard and Keen, 2010), partly the result of inadequate institutions to implement alternate tax regimes. For a majority of these countries, there was a net decline in overall public revenues – a loss in policy capacity – with implications for spending in health, education, or public regulations that can affect primary and secondary prevention of disease.

Turmoil in Labor Markets

At the same time that many countries saw their policy space and capacity erode under structural adjustment, a global reorganization of production was unfolding through the creation of 'export processing zones' (EPZs) in low- and middle-income countries. Industrial manufacturing previously centered in high-income countries began to outsource production to EPZs, which are tax-free and provide a low-paid and often minimally regulated workforce (Martinez, 2004). Most of the world's trade no longer occurs between nations, but between multiple subsidiaries of transnational companies. Much of the value added (and the profit) is captured by the firm at the top of the chain, often in offshore financial centers ('tax havens'), and often by way of relentless pressure on competing suppliers to bear most of the risk associated with investments in plant and equipment and to contain labor and other production costs. Corporations' ability to relocate production to lower cost jurisdictions limits the ability of workers to negotiate better wages and working conditions, and to expand social provision through the political process that was at the core of the postwar compromise between workers and capital in the high-income world. The result: 'most workers are being squeezed' (Woodall, 2006). This is occurring in all countries of the world. Even those in low- and middle-income countries who have seen their incomes rise as a result of the growth in global production chains live in conditions variously described as 'vulnerable' or 'precarious,' where their employment is often informal, temporary, part-time, or generally lacking in adequate remuneration, security, or benefits (Standing, 2011). Social protection programs can compensate, at least in part, for job and labor income losses that result from trade liberalization. However, given the extent of global market liberalization in capital, goods, and services, most of the world's governments find themselves converging on a policy model in which they strive to make their own geographic location as competitive as

possible in international markets. Both labor market 'flexibilization,' with its stress-related health risks, and limits on the taxes that could finance improved health and social protection policies constitute important elements of competition state policies (Schrecker and Labonté, 2011).

Globalization's New Health Challenges: Financial Crises and Austerity

In parallel with the globalization of the 'real economy' of production and consumption since the 1980s, a new form of capital accumulation arose in the rapid growth of a 'financialized' economy. Aided by new digital technologies, investors and financial institutions discovered that it was easier and faster to make money from money than lending it to the 'real economy' of production and consumption. The scale of this financialization is almost hard to imagine, with the value of outstanding derivatives in 2011 exceeding $700 trillion, or more than 10 times the total value of the world's gross domestic product. In late 2011, and despite the 2008 Global Financial Crisis (GFC), this daily arbitrage amounted to almost $5 trillion (Bech, 2012).

The Great Financial Crisis

The proximate cause of the GFC was the collapse of the US housing market, leading to publicly financed trillion-dollar bailouts and countercyclical spending. Public deficits were created to cover the risks taken by private financiers, with one estimate of the total amount of public financing that went into the bank rescues among the G20 countries placing it at $11.7 trillion (Ortiz and Cummins, 2012), several hundred billion of which was direct subsidies. Some of this amount has since been repaid or recovered through sale of government shares in quasinationalized failed banks, although not without large public losses. Less evident but more systemic is the interest rate spreads on what governments and their central banks provide to banks and what they then borrow back to cover this lending, leading to a massive transfer of public wealth to the very institutions and individuals responsible for the GFC (Altvater and Mankopf, 2012).

The depth of global production chains meant that the GFC's credit crunch and subsequent Great Recession rippled rapidly across supply chains in low- and middle-income countries. While there is some worry that this will lead to a rise in extreme poverty (the greatest risk condition for disease) and increased child mortality, the most striking concern is a sharp rise in global unemployment, much of it concentrated among young adults, and creating a surplus (unemployed) labor pool of over 200 million (ILO, 2013). The GFC also accelerated a longer standing trend in rising wealth and income inequalities within and between most nations of the world, notwithstanding some notable exceptions in South America. Although still subject to empirical contestation, such inequalities have been argued to pose a number of health and social risks (Wilkinson and Pickett, 2009). While the GFC has negatively affected the pensions and savings of many of the world's middle and working classes, the 24 million whom investment banks refer to as 'high- and ultrahigh-net-worth individuals' saw their balance sheets decline for a year or two, before increasing by over 20% (Baxter, 2011), a remarkable feat the pre-1929 oligarchs never accomplished. Billionaire wealth rose 20% alone in 2012 over 2011, in what Forbes described as 'a very good year for billionaires' (Forbes, 2013).

The Austerity Agenda

After a brief period of stimulus spending by many of the world's high-income countries and those low- and middle-income countries that could afford it, most governments quickly signed on to 'the austerity agenda': a protracted period of state retrenchment argued as necessary to reduce government debt (much of it incurred to rescue failed banks) and to stimulate economic growth. The key tenets of austerity differ little from earlier structural adjustment (Ortiz and Cummins, 2013). Unlike structural adjustment, the austerity agenda began in those high-income countries that were the epicenter of the GFC before becoming a more globalized set of policy prescriptions with fiscal contractions most severe in the developing world. Although there was little consensus among economists on the wisdom of pursuing austerity, the majority of IMF post-GFC loans pushed for elimination of food and fuel subsidies; wage bill cuts including salaries of education, health, and other public sector workers; rationalizing (reducing) safety net expenditures; and pension reform to delay eligibility. Several countries have been advised to reform their public health systems and increase labor market flexibilization, while many governments are attempting to generate revenue by broadening their consumption taxes to items disproportionately consumed by poor households (Ortiz and Cummins, 2013).

The austerity agenda is expected to have mixed health impacts on populations in high-income countries, on the one hand potentially reducing discretionary expenditures on tobacco or excess alcohol consumption, but on the other hand increasing poverty rates for those in less secure employment settings; homelessness, particularly in the United States; and increased reliance on low-cost, highly processed obesogenic foods. Unemployment- and poverty/insecurity-related stress levels are also predicted to rise; and suicide rates since the crisis have increased by 12–15% in the worst affected European countries, at the same time that health and social protection financing has been dramatically cut back and user charges imposed on many services (Stuckler and Basu, 2013). The health implications of austerity in low- and middle-income countries will likely follow that which accompanied earlier, regional financial crises: increased social stratification and inequalities; reduced food intake, health care utilization, and education expenditure; and increased morbidity and mortality, experienced first and worst by women, rural populations, and the poor.

A Deepening Neoliberalism

It is important to understand these recent globalization health risks as an extension of a 40-year uncontrolled experiment in neoliberal economic theory. From neoliberalism 1.0 (structural adjustment) to 2.0 (financialized economy) to 3.0 (austerity agenda), the rationale first proposed by Hayek – that the economy is too complex for government regulation

and best left to an open, unfettered market with minimal state interference – has deepened and proved resilient even in the face of its failures. The present fiscal contraction of austerity is due, in no small measure, to decades of advice to developing countries by the international financial institutions (the IMF and WB) to keep taxes low to attract foreign investment, and tax cuts, notably among the high-income Anglo-American liberal economies and defended in the name of debt reduction and international competitiveness, that saw substantial declines the 1980s in marginal tax rates (paid by highest income earners) and corporate taxes, and increases in regressive consumption taxes. There would be no fiscal crisis and no need for austerity in most of the world's countries if progressive taxation had been retained. Even in those countries facing structural deficits, such as Greece, or reliant on aid transfers, such as many sub-Saharan African countries, liberalization of capital markets and global banking integration (including branches in all the world's tax havens) continue to allow companies and wealthy elites to avoid taxation almost altogether. The African continent has lost more wealth over the past 40 years in illicit capital flight, partly due to criminality and corruption but most of it involving commercial tax evasion, than it has received in foreign aid (African Development Bank, 2013).

The two international institutions most implicated in the diffusion of neoliberal economics, the WB and the IMF, have begun to accept the empirical evidence of its shortcomings, calling for greater government caution in implementing austerity measures, partly in recognition of the 'fiscal multiplier' effect of government spending. In times of recession, public spending yields far more economic return to the 'real economy' of production and consumption (through purchasing and employment) than do tax cuts intended to spur private sector investments. Conservative estimates of this fiscal multiplier find that every dollar in public spending generates between 1.6 and 1.7 dollars in economic growth (Stanford, 2013), with recent estimates of European public spending by sector showing much greater multiplier impacts for public investments in health, education, and environmental protection (Reeves et al., 2013). The WB and IMF are also now cautioning against 'extreme austerity' and calling for higher taxation rates, especially for 'ultrahigh-net-worth individuals.' In 2012, the world's 1426 billionaires between them had as much wealth (USD 5.4 trillion) (Forbes, 2013) as the entire continent of Africa (USD 2.3 trillion) and India (USD 3.2 trillion) (Shorrocks et al., 2012). Given Africa's and India's 2011 combined population of 2.2 billion, this represents an inequality ratio of roughly 1 500 000:1.

Although this surge in private wealth has led to new philanthropies, some of them focused on global health issues, these are driven by individuals and their own ideas about how their wealth should be distributed, rather than through tax-funded, publicly representative, and accountable processes. A 2013 US review of econometric studies found that raising marginal tax rates from their present historic low of 35% to their previous high of 68% would have no statistically significant impact on factors driving economic growth, but would reduce poverty, inequality, and stimulate growth through public spending (Fieldhouse, 2013). Similar findings exist for imposition of global taxation measures, such as a financial transaction tax that, by one study's estimate and if applied at a very low rate (.05%, or 5 cents on every 100 dollars) on every currency transaction, would generate over US $8 trillion in annual revenues (McCulloch and Pacillo, 2011). Globalized capital calls for global systems of taxation, toward which some of the world's governments are now slowly turning their attention.

Simply stated, we do not have a problem of excess public debt. We have a problem of inadequate private taxation. We do not have a crisis of scarcity. We have a crisis of extreme inequality. These conditions and the health risks they pose are not 'natural,' but the result of policy choices for which there are alternatives.

Global Governance for Health

There is nothing inherently unhealthy in globalization as first defined: the growing interdependence of peoples across the world, through increased economic integration, cultural diffusion, and travel. It is the particular economic form of this interdependence – the 'neo'liberalization of capital from the checks and balances that once existed when capital was confined within national borders – that is problematic, not only for public health. It has been argued for some time that the crisis facing contemporary globalization is that national governments and powerful elites have created binding and enforceable rules for a 'free' global economy without a global governance system capable of regulating that economy for a social purpose. That may be slowly changing.

Putting More Health in Trade

There is some evidence that WTO panels are increasingly accepting the importance and legitimacy of public health arguments in trade disputes, albeit only if there is no obvious trade discrimination involved. A 2010 case involving a tobacco dispute between Indonesia and the United States is illustrative. To comply with domestic legislation to prevent adolescent smoking, the United States banned imports of flavored cigarettes. Indonesia argued that the domestic legislation, by exempting 'menthol' from the list of flavors, discriminated against its clove cigarettes in favor of US-manufactured menthol cigarettes, which are the favored choice of American teens. This constituted a violation of WTO rules on national treatment (there should be no discrimination against 'like' imported goods). Indonesia further argued that there were 'less-trade-restrictive' ways (another WTO requirement) to meet the public health goal of reducing adolescent smoking than a ban on clove cigarette imports. The WTO dispute panel ruled with Indonesia on the first argument (nondiscrimination) but with the United States on the second (agreeing that a ban was a necessary public health policy). Provided there is no obvious discrimination, public health regulations appear to have growing latitude within (at least some) WTO (McGrady, 2012). There is also greater public health attention being given to proposed trade and investment treaties, with efforts to ensure that before such treaties are finalized, public health concerns are given due consideration, and that 'policy space' for future public health regulation is assured, e.g., regarding trade or investment in food, alcohol, or other health-damaging commodities. The potential for a healthier governance of

trade and investment treaties, however, remains constrained by the secrecy in which the treaties are negotiated, the privileging of business interests over public interests in informing government positions during negotiations, and the still-dominant assumption that liberalization is an inherently positive development for all countries involved. As argued, this is not a universally held or observed assumption.

Building Up the Social Protection Floor

In a different vein, the International Labor Organization is actively promoting a 'Social Protection Floor Initiative' to encourage countries to systematically build up their social protection systems. The argument for such an initiative is simple and compelling – social protection equitably redistributes wealth, opportunity, and health – and it is rooted in globally shared principles of social justice and human rights. It is supported by a large number of UN agencies, development banks, and government development agencies. There are glimmers of its implementation in different parts of the world: extended health coverage (now embraced by the WHO and the WB in the call for 'universal health coverage'), social cash transfers, and public sector and rural employment guarantee schemes. The Initiative highlights the important role that a strong and strongly tax-supported social protection system can play in times of economic crises. Its implementation, however, rests on countries' willingness to increase rather than decrease progressive taxation (a race to the top, rather than to the bottom), and, in the case of many sub-Saharan African countries, an increase in the very low level of royalties or 'rents' charged to transnational extractive industries, and imposed during neoliberalism 1.0 as structural adjustment conditionalities (OSISA, 2009). Finally, while the Social Protection Initiative offers countries good technical advice, it does not and cannot address the political will needed to implement such schemes.

Moving Health Higher Up the Foreign Policy Agenda

Efforts to create that political will can be found on two fronts: governmental initiatives to raise health higher in the foreign policy positions and negotiations of states, and the international campaigning of civil society organizations. Regarding the first, there have been several recent initiatives to improve foreign policy coherence for health. The Foreign Policy and Global Health initiative launched in 2006 by the foreign ministers of Brazil, France, Indonesia, Norway, Senegal, South Africa, and Thailand and renewed in 2011, as one example, encourages nations to broaden the scope of national foreign policies to integrate health concerns in a sustainable way and not as a crisis driven 'one-off' (Ministers of Foreign Affairs, 2007). Resolution 63/33 'Global health and foreign policy' adopted by the UN General Assembly in November 2008 further recognizes the "close relationship between foreign policy and global health and their interdependence" and urges "member States to consider health in the formulation of foreign policy" (United Nations General Assembly, 2009). Several nations have pursued this aim through the development of coherent strategies (Labonté and Gagnon, 2010) or efforts to create platforms for a 'health-in-all-policies' approach to their foreign affairs. Despite its recent global prominence, however, health is still not typically prioritized in the foreign policy agenda of most countries, and when it is, it is driven by traditional 'high politics' of security or economic risks due to pandemics or the spread of drug-resistant diseases. The continuing funding crisis of the WHO, and its reliance on extrabudgetary (nontithed) funding from governments and private sector donors for much of its operational budget, weakens its ability to provide leadership on global health governance initiatives that may go against the short-term interests of powerful nations or corporate actors (Vaughan et al., 1996).

Supporting Civil Society Activism

Civil society activism, often aligned with organized labor movements, has been in the forefront of challenging the damaging social, environmental, and health impacts of neoliberal globalization. There have been some successes. The persistence of health activists in government and civil society moved tobacco control from indisputable evidence of smoking's harms to smoking restrictions, pricing measures, and other policies aimed at shifting cultural norms – always in conflict with tobacco transnational companies. South Africa's Treatment Action Campaign helped to break the impasse between new regimes of intellectual property rights and access to antiretroviral medicines, aligning with international groups mobilizing for a 'just' globalization and invoking international human rights treaties in their advocacy. A powerful network of 'peasant' organizations arose in Latin America in the 1990s, and has inspired similar mobilizations globally, linking together activism on agroecology, right livelihoods, food security, social protection, gender empowerment, indigenous rights, and environmental sustainability. In the same decade, a network of international civil society organizations defeated the Multilateral Agreement on Investments in 1998, an Organization for Economic Cooperation and Development (OECD) effort to further and more deeply liberalize cross-border capital flows than had been accomplished in WTO negotiations, although liberalized investment rules are increasingly being inserted into regional and bilateral trade treaties. Civil society activism demands persistence.

Conclusion: Accepting the Environmental Limits to Growth

While providing global health activists with a cautious optimism of the spirit, recent government and continued civil society activism in global health has yet to offer a sustained challenge to neoliberal globalization. Even if governments and activists succeed in curbing the predatory excesses of the financialized economy (neoliberalism 2.0), and exposing the inequitable and economically ineffective austerity agenda (neoliberalism 3.0), it will have to contend with ecological limits of returning to a pre-GFC 'real economy' of production and consumption. As the UK Commission on Sustainable Development noted in its 2009 study, "there is as yet no credible, socially just, ecologically sustainable scenario of continually growing incomes for a world of nine billion people" (Jackson, 2009). Indeed, the two sectors that are most driving climate change are energy production/consumption and transportation – the two activities central to our globalized economy.

Borrowing from an earlier study on the social dimensions of globalization, the Globalization Knowledge Network of the 2008 WHO Commission on Social Determinants of Health concluded that an equitable global health would only be secured under the 'three R's': systematic *resource* redistribution between countries and within regions and countries to enable poorer countries to meet human needs, effective supranational *regulation* to ensure that there is a social purpose in the global economy, and enforceable social *rights* that enable citizens and residents to seek legal redress (Labonté et al., 2007).

Globalization and Human Trafficking

Mónica Méndez, House of Mentoring & Empowerment, Inc., Orlando, FL, USA

Abstract

Since the 1990s, globalization, driven by economic interests and improved communications, technology, and transportation, has resulted in a more interconnected environment that allows human trafficking to thrive, while helping to combat it at the same time. The unequal social and economic conditions around the world perpetuate the idea that some humans are commodities that can be sold and traded in world markets. The lucrative nature of human trafficking has resulted in the growing demand for humans from countries of origin where the supply of people is both high and the transactions quick and low risk as a result of technology, advanced communication, and faster transportation. The demand for people comes from within the supply countries and from both developing and developed countries as the need for labor and the sexualization of primarily women and children continue to breed inhumane uses of humans.

This article defines globalization and human trafficking and then shows how the former has perpetuated and assisted in the evolution of the trafficking of people. At the same time, globalization has supported governments, nongovernmental organizations (NGOs), and individuals in combating human trafficking.

Globalization

As world economies, transportation, and communications expand, the world becomes increasingly integrated and interdependent. Commonly referred to as 'globalization,' this interconnectedness includes everything from the integration of governments, economies, transportation, and business to the melding of cultures, laws, and social movements. Beginning in the late nineteenth century, globalization intensified as a result of industrial, communications, technological, economic, and transportation advances (Wolf, 2001). It has played a key role in the growth of national economies and international businesses, both legitimate and illegitimate, primarily through the continuously emerging science, technologies, and communication mediums that facilitate the free flow of people, goods, services, and ideas (Shangquan, 2000; Stohl, 2008). The concept of globalization is complex, but it may be broken down into economic, cultural, and political components to better understand it.

Economic globalization refers to the connectedness of economic activity, such as cross-border trade and the spread of technologies, that creates global interdependence in markets, capital, and commodities (Shangquan, 2000). Olteanu and Radoi (2010) describe it as the internationalization of economies where liberalizing markets have created intense competition for control and location of the labor markets. Economic globalization can result in people, who have been displaced by agricultural modernization, needing to seek other lines of work in their own and other countries, and it can create corruption and violence, while destroying social norms, through rapid economic changes (Bales, 2004). Cultural globalization refers to the diffusion of ideas, values, and ways of life, as well as the creation of a global conscience, through technology, communication mediums, and transportation (Moghadam, 2005). It implies that the almost instantaneous exchange of ideas creates more connectivity, interaction, and interdependence among people of different cultures and can refer to the heavy influence of Western cultures on other societies. Finally, political globalization focuses on multilateralism and the increased influence of public policy across borders, affecting governing doctrines that deal with human rights, energy, the environment, and political governmental models, such as democracy (Moghadam, 2005; Zaleski, 2006). The connectivity that exists as a result of the tools of globalization (i.e., science, technology, and communication mediums) breaks through the time and space limitations that, before globalization, created barriers to the exchange of capital and commodities. Economic markets, businesses, intra- and intercontinental communications, and transportation are now more efficient and more accessible to people and regions who previously lacked such access.

Globalization's effects are vast and are both positive and negative, especially considering that different social groups are affected in diverse manners (Lee, 2011). From the positive perspective, global communication allows people to connect to one another more efficiently, making business, politics, and social exchanges more immediate and profitable by saving both time and money. The power to connect people and its potential to spread wealth are also seen as a means of providing opportunities to individuals who, because of location, language barriers, and/or economic situations, have little to no access to education and employment (Mohr, 2012). In addition, due to globalization more countries, individuals, and businesses have access to financial lending, allowing for improved social and civil infrastructures, a higher standard of living and access to markets that were not open before. Finally, people are exposed to other cultures and ideas, and they are more aware of world social problems and solutions.

Other perspectives argue that globalization increases social inequalities, specifically the gap in income distribution, and it allows for the continued exploitation of people, both in and out of the labor market, who are not as connected or protected as others (International Labour Organization, 2008; Mohr, 2012; World Commission on Social Dimension of Globalization, 2004). The interests of high-income countries drive the interests of the rest of the world, leaving low-income countries to bear the brunt of the negative economic, labor,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64131-4

environmental, and social consequences of globalization. The latter include the perpetuation of poverty, social inequalities, the oppression of women and other minorities, and the lack of afforded protections to these groups. Marginalized people – those who are impoverished, discriminated against, homeless, incarcerated, and otherwise socially and economically excluded – are particularly negatively affected and victimized by globalization (Hepburn and Simon, 2013; Polakoff, 2007).

Although globalization has improved many aspects of contemporary life around the world, it has also had a far-reaching and negative effect on one of the oldest and most egregious human rights offenses: human trafficking. The negative effects of globalization are in many ways embodied by the sexual exploitation of youth and adults. Interconnectedness has made it easy for sexual exploiters to connect to and sell to buyers of infants, children, youth, and adults in a sex industry that highlights the intersectionality of race, gender, and economics. The victims and survivors of these crimes – especially women and children – often do not have the means to fight back due to poverty and the lack of other protections, including a lack of power, opportunity, and a growing inequality gap (Farr, 2005; United Nations Office of Drugs and Crime, 2012).

Human Trafficking

Human trafficking has been defined by numerous governmental entities in an attempt to clarify what it looks like, who is involved and how it is happening. Although there are variations of the definition and debate about what should and should not be included (Lee, 2011), a widely accepted definition found in the Protocol to Prevent, Suppress and Punish Trafficking in Persons especially Women and Children (hereafter the Trafficking Protocol) (2000) defines human trafficking as the

> recruitment, transportation, transfer, harbouring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labour or services, slavery or practices similar to slavery, servitude or the removal of organs…(p. 42)

There is a clear distinction between smuggling, which is a crime against state borders, and human trafficking, which is a crime against a person. The definitions of human trafficking that are widely used have made efforts to emphasize that the important aspect of trafficking is the crime against the person (Nagle, 2008).

Human beings have been seen as commodities since before globalization emerged, and the tools of globalization have made it easier for human trafficking to flourish in markets across the world. The increased ability to exchange money, communicate and sell through the Internet, and send commodities and people across borders faster than ever has made the trafficking of humans the third most widespread business for organized crime in the world, right behind drugs and arms dealing (Nagle, 2008). Since the beginning of the twenty-first century, more international attention has been given to human trafficking. Yet it is important to remember that attempts to combat it through antislavery movements and laws have been continuous, from the Universal Declaration of Human Rights in 1948 to more recent resolutions and legislation encompassing the rights of women and children and others. (see the 1956 Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices Similar to Slavery; the 1948 American Declaration on the Rights and Duties of Man; the 1957 Abolition of Forced Labour Convention; the International Covenant on Civil and Political Rights; the Convention Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment; United Nations General Assembly Resolutions on Traffic in Women and Girls; the 1996 Final Report of the World Congress against Sexual Exploitation of Children; the 1995 Fourth World Conference on Women in Beijing; and the 1991 Moscow Document of the Organization for Security and Cooperation in Europe).

As a result of the transnational component of human trafficking, increased awareness of the issue and the increasing interconnectedness of countries, the fight against human trafficking has been progressively seen as a global responsibility and a gross violation of human rights, which is a contrast to what it was seen as in the 1980s as a 'women's issue' that was given little attention and funding (Lee, 2011). As such, international entities have dedicated conventions and protocols to the issue of trafficking. In 1998, at the UN Commission for Crime Prevention and Criminal Justice, the United States presented a resolution on the trafficking of women and children that called for the creation of protocols under the United Nations Convention against Transnational Organized Crime (Hyland, 2001). As a result, the United States and Argentina drafted the Trafficking Protocol in 1999; it became the first and main comprehensive international instrument to combat human trafficking. The 2000 final version of the Trafficking Protocol, first put into effect in 2003, was the first enforceable instrument to provide a universal definition of human trafficking, making it easier for countries to work internationally, and was the first to provide tough laws and protections for survivors of trafficking.

As defined by the International Labour Organization (2012), the U.S. State Department (2012), and the United Nations General Assembly (2000), human trafficking takes on many forms in both labor and sex trafficking. For instance, labor trafficking encompasses forcing, deceiving, coercing, manipulating, and/or threatening individuals into working on fishing boats, in manufacturing factories, private homes, agriculture, construction, massage parlors, and/or other businesses such as nail salons, restaurants, call centers, and hotels. Individuals may cross no borders, or travel through national or continental boundaries under the guise of working in legitimate businesses but then find themselves trapped. Traffickers hold victims and survivors without justification, under threat of harm to themselves or their families, or under the guise that the survivor owes the trafficker money for transportation, housing, and any food used during the working period. Traffickers may

also operate as legitimate businesses that take control of indigenous land or local farmers' lands and force the people to work on the land for little to no pay in order to buy back the land, knowing full well that the interest included in the price of the land accumulates faster than workers can accumulate pay.

Another means of labor trafficking, and one of the most prolific in the world, occurs through debt bondage, which is when an individual is born into the debt of a family, acquires a loan that is unpayable, or is deceived into traveling for work and then owes the money for the travel (Siddharth, 2009; United Nations, 1956). As time passes, the victims and survivors may be unable to pay back the money, and debt accumulates everyday that passes. Debt bondage has existed throughout history and continues to exist today primarily in developing countries, including South Asian countries, where caste systems enslave families generation after generation, and in South America and Africa, where banking systems, legitimate loan and credit sources are often scarce. However, debt bondage can exist in developed countries in the form of travel debt, drug debt, and domestic servitude. For example, sexual exploitation can occur when an individual is forced to sell her or his body for sex to pay for drugs she or he has used. Debt bondage is one of the most common forms of forced labor and has been outlawed internationally, but, like many other forms of trafficking, it persists as a result of inadequate social, political, and economic safety nets available to victims and survivors.

Forcing children and handicapped people to beg on streets is also a common form of labor trafficking (Cherneva, 2011). In some instances, children who might be healthy are purposely maimed to seem more sympathetic; for example, some homeless or poor children in South Asia are purposefully blinded for this reason. Similar to begging, a traveling 'sales crew' is a relatively new human trafficking method, being tracked in some countries, including in the United States. In these situations, teenagers and young adults are manipulated into working for little to no money by traffickers who transport them to varying locations to have them sell magazines, candy, or other trinkets under the guise of working for a nonprofit or a scholarship. Victims work long hours and are charged for any water or food they use, leaving them close to nothing in pay. There are few repercussions for the traffickers and few resources for the survivors as a result of social inequalities and insufficient laws or understanding surrounding of the issues.

Sexual exploitation is another type of human trafficking that is primarily, but not exclusively, been seen as affecting women and children (United Nations Office on Drugs and Crime, 2006, 2009, 2012; International Labour Organization, 2012). According to the ILO, sexual exploitation is a form of labor trafficking that can include infants, children, teenagers, and adults being sold into the pornography industry, brothels, hotels, massage parlors, strip clubs, the street, and homes around the world. Sexual exploitation occurs differently across the world, but the lack of opportunities for families and individuals, as well as gender and social inequalities, feeds the need to find some form of livelihood. In societies where women and girls are seen as economic weights on their families, girls and teens are sometimes sold to brothels as a means of disposing of them or to make them support their families. In the United States, domestic trafficking is aided by the hypersexualization of girls, the sexual abuse of girls, a lack of opportunity to escape abuse and poverty, and a system that is not yet ready to assist these survivors. Social factors, such as community rejections of gay, lesbian, bisexual, or transgender individuals, also make it easier to exploit individuals in the sex industry. Combined with poverty, these factors make individuals in all countries susceptible to the cons and traps of traffickers.

Adoptions, forced marriages, military service, and organ trafficking are other forms of human trafficking that are not necessarily included in some definitions of trafficking, including the International Labour Organization's (2012) definition. Adoptions can turn into human trafficking when children are abducted from their families, families are deceived or coerced into giving up their children for adoption, or families sell the children to adoption agencies in order to survive. As a result of war, civil conflicts, natural disasters (e.g., Haiti's 2010 earthquake), and other events, the practice of selling children, especially via international adoptions, is not easily measurable or preventable.

Forced marriages of women and girls are another form of human trafficking that defines a situation where one of the spouses, usually a woman or girl, does not have the ability to refuse marriage (United Nations, 1956). Women and girls as young as 8 years of age can be forced to marry men in exchange for dowries or because the girls and women are seen as less valuable than sons. This practice is common in the Middle East, South Asia, and Africa (Bokhari, 2008). Mail-order brides, common in areas of Russia, Eastern Europe, and South Asian countries, are also considered forced marriage because the women are deceived or forced into making themselves available to the highest bidder as a result of organized crime and/or poverty.

Forced military service of boys, men, women, and girls is another type of trafficking that may occur out of threat, force, coercion, deception, and manipulation. It has been occurring since World War II, but the social disruption caused by globalization, prolonged armed conflict, and the spread of diseases has been seen as causes for the increase in the use of child soldiers (Tiefenbrun, 2007). Children as young as 8 years of age have been identified as child soldiers, and the girls and boys who are forced into military services also often serve as sex slaves for the troops (United Nations Office for the Coordination of Humanitarian Affairs, 2007). Armed conflict, illness, and poverty may leave orphaned children who are then forced to serve in military organizations supported by governments, paramilitary organizations, or rebel groups.

Finally, organ trafficking must be included in this sometimes-excluded group of trafficked individuals. The trafficking of organs may occur with or without the consent of the victim, and, when one considers that consent may mean a poor individual from a developing country that sees no way of surviving than through the sale of her or his organs, consent is nothing more than exploitation by those involved in the globalization of organ transplants (Scheper-Hughes, 2000; Budiani-Saberi and Delmonico, 2008). Deception in organ trafficking could occur when a person believes she or he will be paid for the organ and is not paid or is paid less than the expected price, or when the person does not realize that she or he agreed to give up an organ. Individuals from poor developing countries, migrant workers,

homeless individuals, and illiterate individuals are some of the target victims of this type of trafficking (Budiani-Saberi and Delmonico, 2008). Everyone from the recruiter of the victim to the medical professionals who remove the organs to the individuals who buy for the organ banks is involved in the illegal trafficking of organs; however, due to a lack of systemic data and laws, the scope of the problem is not well known or understood.

Because people are seen as durable commodities that can be sold, exchanged, and/or traded in world markets for very high prices, human trafficking is extremely lucrative. For example, a drug or weapon sale provides a one-time profit. However, humans can be used and sold as many times as the individuals can withstand, with continuous gains going to the traffickers. According to the ILO, some estimates of human trafficking profits exceed US$31 billion a year (2005).

Estimates of Human Trafficking

Human trafficking takes on different forms around the world and estimates vary as to how many people are affected, what countries they originate in, and to what countries they go. In fact, there is much criticism about the methodologies used to gather estimates and the poor data propelling the movement to end trafficking (Sanghera, 2005; Lee, 2011). Estimates on the condition of human trafficking vary as a result of its different definitions that come from varying interests and stakeholders, different methodologies for gathering and analyzing data, a lack of systematic data gathering, varying access to institutional, country, and organizational data, and the use of different measures. In addition, some laws around the world may only apply to and define certain types of trafficking, types of victims and survivors (e.g., women and children but not men), and enforcement tools, making it difficult to obtain any data or any reliable data (United Nations Office of Drugs and Crime, 2006, 2009). Finally, as a result of a lack of protection for the victims and survivors of trafficking, as well as internal conflicts and discrimination, survivors of trafficking and their allies may not be able to report the trafficking out of fear for themselves and their families. In countries where governments do not have a history of victim services and comprehensive laws, the barriers to reporting are very real and can result in low levels of reporting. However, it is still important to outline what different entities around the world estimate when it comes to the trafficking of humans.

In 2006, the United Nations Office on Drugs and Crime provided its first Trafficking in Persons Global Report detailing trends of human trafficking in 127 countries of origin to 137 destination countries from 1996 to 2006 (United Nations Office on Drugs and Crime, 2006). The report outlined three basic distinctions among countries that are not mutually exclusive when it comes to trafficking in humans: countries of origin (from where the victims and survivors come), transit countries (countries through which transportation of victims and survivors is common), and destination countries. According to the findings, Albania, Belarus, Bulgaria, China, Lithuania, Nigeria, Moldova, Romania, Russia, Thailand, and Ukraine have the highest incidences of human trafficking when it comes to origins of victims and survivors. Albania, Bulgaria, Hungary, Italy, Poland, and Thailand are the most used transit countries, and victims and survivors of trafficking are most likely headed to Belgium, Germany, Greece, Israel, Italy, Japan, Netherlands, Thailand, Turkey, and the United States of America.

The ILO's most recent publication on human trafficking (2012) is based on a study conducted from 2002 to 2011 on the estimate of people forced into labor in the world. It estimated, conservatively, that there were about 20.9 million people around the world who were victims and survivors of forced labor, including sexual exploitation. It is a conservative estimate because human trafficking is a hidden crime not easily measurable and because it does not include trafficking for the removal of organs or numbers on forced marriage or adoption unless the practices lead to forced labor situations. The report further divides the 20.9 million into what sectors exploit them: 18.7 million by the private sector, encompassing 4.5 million in the sex industry and 14.2 million in agriculture, construction, domestic work, and manufacturing. Governments, through state-imposed forms of forced labor, exploit the remaining 2.2 million. This study is an example of how definitions of exploitation include and exclude different types of human trafficking; it is meant to include labor practices only, ignoring some important forms of human trafficking while including what other researchers may not consider forced labor by other definitions (i.e., state-imposed labor through prisons).

In contrast, the Walking Free Foundation conducted its own research on the prevalence of what they term modern day slavery that includes slavery, slavery-like practices (e.g., forced marriage, debt bondage, children forced into armed conflict), human trafficking, and forced labor (2013). The study relies on three definitions of modern day slavery provided by the 1956 Slavery Convention, the 1930 Forced Labour Convention, and the 2000 United Nations Trafficking Protocol. According to the Global Slavery Index report of 2013, there are an estimated 29.8 million people exploited through modern day slavery. The index provides estimates for 162 countries and showed that the highest prevalence of slavery (in order) was in Mauritania, Haiti, Pakistan, India, Nepal, Moldova, Benin, Cote D'Ivoire, The Gambia, and Gabon. When considering numbers in absolute terms, however, the countries with the highest number of slaves (in order) are India, China, Pakistan, Nigeria, Ethiopia, Russia, Thailand, the Democratic Republic of Congo, Myanmar, and Bangladesh. The latter group of countries, those with the highest number of slaves, accounts for up to 76% of the total estimated number of 29.8 million people enslaved worldwide.

These two reports are examples of often cited statistics on the current status of human trafficking, and, as is evident, they show how widely different the perspectives on who is a victim and survivor of human trafficking and what types of trafficking are most prevalent and where.

The Victims and Survivors

The victims and survivors of human trafficking across the world come from varying backgrounds and are sought for different types of exploitation. As previously mentioned, several factors make trafficking statistics and survivor identification difficult. What reports have found across the board is that human

trafficking appears to be intraregional, meaning that the traffickers are usually trafficking people of their same country or regional area (United Nations Office on Drugs and Crime, 2006, 2009; International Labour Organization, 2012).

When it comes to transnational human trafficking, the data on the type of exploitation and its estimate vary (United Nations Office on Drugs and Crime, 2009; International Labour Organization, 2012). As a result of most of the laws around the world focusing on child victims and victims and survivors of sexual exploitation, the majority of victims and survivors of trafficking who were identified in 2006 in 61 countries were 66% women and 13% girls, with men and boys only being identified in 12 and 9% of the cases, respectively (United Nations Office on Drugs and Crime, 2009). There were only slight changes in the 2012 United Nations report that indicated that 59, 17, 14, and 10% of trafficked survivors were women, girls, men, and boys, respectively. When the type of exploitation was identified, statistics showed that 79% of the victims and survivors were sexually exploited, a contrast to the 2012 ILO statistic showing that about 24% of its cases concerned sexual exploitation. However, the exploitation of men and boys may not be as visible or measurable as a result of their lack of inclusion in laws. The United Nations, ILO, Amnesty International, and others have recorded quantitative and qualitative data on the trafficking of men and boys in the shipping, fishing, agriculture, and manufacturing businesses, as well as soldiers in wars, domestic servitude, and sex industries.

The effects of labor and sex trafficking on individuals trafficked tend to be devastatingly negative (Zimmerman et al., 2011; U.S. Department of State, 2012). The physical, psychological, verbal, and sexual violence and torture experienced by trafficked individuals cause irreparable, long-lasting physical and psychological damage to individuals (Hossain et al., 2010). Trauma, sexually transmitted infections, anxiety, depression, post-traumatic stress disorder, alcohol and substance abuse, unwanted pregnancies, malnutrition, and social ostracism may all occur to one individual. For children, there is the added component of stunted physical, educational, and psychological growth, creating – if they survive – adults who have a hard time thriving in a healthy society. The victims, the survivors who die in the process of trafficking, suffer the ultimate effect of trafficking. While the international community has a hard time estimating the number of individuals being trafficked, it has a harder, even impossible, time estimating the number of individuals who die while being trafficked.

The Exploiters: Organized Crime, Pimps, Businesses, and Buyers

Researchers gathering data from criminal justice organizations around the world have shown that the international trafficker networks in the countries of origin are those controlling and driving the trafficking (United Nations Office on Drugs and Crime, 2009). Traffickers in the countries of origin are best able to gain the trust of the victims and manipulate the local crime networks, which sometimes include local law enforcement and politicians, to keep victims under control. However, in some parts of the world, like Eastern Europe, there are organized crime entities that consist of national and transnational groups that make the trafficking possible (Surtees, 2008).

Research on the continued existence of trafficking shows that traffickers must depend on a wide network of legal and illegal socioecological participants, including politicians, government workers, law enforcement, nonprofit organizations, and communities that survive on the trafficking and exploitation of humans (Surtees, 2008). For example, in a study of 91 Chicago pimps done by Raphael and Myers-Powell (2010), pimps mention that the only way that they can operate is through the bribing of police officers, cab drivers, hotel managers, and some politicians. As a result of increased globalization, these networks have been made stronger and faster than before the existence of our current communications and transportation tools.

For traffickers, keeping victims and survivors of trafficking under control is also a vital part of the process (Surtees, 2008). Mind games, physical harm, threats on family, threats of death, isolation, and debt are tools that traffickers use to keep survivors trapped (Bruce and Failla, 2004; Surtees, 2008). Trauma bond, or Stockholm syndrome, may also play a part in a survivor staying in the trafficking situation (National Colloquium, 2012). For example, girls who run away from home and are picked up and used by traffickers for sex exploitation may see the trafficker as a savior who has sheltered, fed, and provided them clothing and, most of all, provided them the love and attention that their family and community failed to provide. In these situations, the survivor is psychologically chained to the trafficker.

Globalization and Human Trafficking: Connectedly Thriving

The trafficking of persons is facilitated by social and economic conditions around the world that treat humans as lucrative and durable commodities that can be traded in markets. Globalization has enhanced the need for a cheap labor market for different sectors of society and, as governments, industries and people compete for footing in newly emerging industries and markets, groups of people find themselves exploited in a process that appears to leave human rights behind (Nagle, 2008). Poverty, underdevelopment, and a lack of opportunity or movement in social classes are but a few factors that add to the ability of traffickers to coerce, force, manipulate, and/or threaten people into trafficking (International Labour Organization, 2008; Mohr, 2012; United Nations General Assembly, 2000; World Commission on Social Dimension of Globalization, 2004). In fact, the displacement caused by wars, natural disasters, technological advances that replace humans, and the transient economies created by rapidly changing economies, force people who have no opportunities to take risks that result in labor or sex exploitation. In addition, trafficking thrives in countries that devalue and discriminate against women and children, providing few legal and social protections for their exploitation in both the labor and sexual commercial realms (United Nations General Assembly, 2000; Walk Free Foundation, 2013). When racial discrimination is recognized as an important variable, also affecting who is trafficked, the effect of globalization on trafficking is made much clearer.

The negative consequences that arise from the perpetuation of human trafficking through globalization includes the faster and more extensive spread of sexually transmitted diseases and infections, the tearing apart of families and communities through better and faster transportation, the breakdown of small, local economies, the further dehumanization and sexualization of women and girls and continued intergenerational violence and abuse experienced at a faster pace by those who are survivors of trafficking. These are a few of the negative results of human trafficking in general, but the increase and growth of globalization has made these results come in a faster and more interconnected manner. The labor force that emerges from inequalities around the world provides an almost free supply for the high demand of all kinds of labor, from sex work to agricultural work. The same tools that have been used to open markets and economies and spread ideas are used to exploit and manipulate individuals and communities who may not have access to these tools and are often oppressed within their regions.

Combating Trafficking in the Midst of Globalization

Although globalization has made it possible to interconnect countries, laws, economics, and societies, it has also facilitated trafficking itself (United Nations General Assembly, 2000). The efforts to decrease and eliminate the trafficking of humans, up to this point, have been fragmented by noncollaboration among countries and regions and diminished by faster and tech-savvy traffickers who do not have to stay within the boundaries of jurisdiction and laws to run their businesses (United Nations Office of Drugs and Crime, 2006). In addition, the trafficking efforts that have taken place thus far are driven by moral laws and agendas that have, at times, turned the tables on the victims and survivors trafficking, viewing them and their 'choices' as the problem instead of centering on the social problems that forced them into sex work, illegal migration, and exploitation (Lee, 2011; Weitzer, 2007).

According to the United Nations Global Report on Trafficking in Persons (2009), this millennium has seen an increase in the number of countries that have taken a stance against trafficking by implementing the Trafficking Protocol; 63% of the 155 countries on which it reported had, by 2008, passed laws against human trafficking that covered the major forms of trafficking defined in the protocol, while 16% had passed some laws that covered at least part of the definition components. With more than half of the 155 countries having established special trafficking police units and national action plans, the strategy for combating trafficking is evolving, especially when compared to a 2003 statistic, which tallied only 35% of countries as having specific laws on the trafficking of persons. Not all of the countries that have tough, comprehensive laws and successful prosecutions of traffickers are, however, high-income countries (United Nations Office on Drugs and Crime, 2009). In other words, national will, not wealth per se, is a driving force for combating trafficking.

In recent years, the fight against human trafficking has shifted into a crime control model that centers on the geopolitical, economic, security, and moral concerns of some of the countries controlling globalization. According to Lee (2011), the crime control antitrafficking movement has centered on five aspects: antiprostitution, securitization, criminalization, militarization, and privatization, all of which are directly connected to those who hold power in the current world of globalization. Antiprostitution and securitization have both directly and indirectly put the weight of trafficking on the victims and survivors; they are blamed for sexual exploitation and immigration issues that, to some groups, are at the root of trafficking. Criminalization takes into account the transnational crossing that globalization has broadened; however, criminalization, although referring to increased attention to organized crime, has also increased the immigration tensions from developing countries to developed countries (i.e., Latin Americans immigration to the United States). The latter three aspects of crime control, as defined by Lee (2011), continue to redefine victims and survivors of trafficking as 'worthy' and 'unworthy' and true victims vs criminals (Bosworth, 2007).

Globalization has also made the militarization and privatization of crime control in human trafficking more efficient. In an attempt to control the aspects of crime that are deemed to be affecting trafficking, countries, like the United States and the United Kingdom, have begun to militarize their borders so as to stop the intrusion of borders (Lee, 2011). Technology that includes advanced surveillance and communication methods has expanded countries' abilities to fight what they see as the underlying problems in human trafficking. However, since it can be difficult for governments themselves to provide the militarization and technological advances needed for combating trafficking, a new industry for private enforcement has emerged in the global markets (Bosworth, 2007). These management, technological, and policing organizations work transnationally in order to ensure that the criminalization, securitization, militarization are all taking place according to the definition of human trafficking accepted by the underlying power (Lee, 2011).

Although the methods of combating human trafficking have increasingly put the onus of the crime on the survivors and victims, there have also been increases in assistance to these victims and survivors. Victim services for survivors of human trafficking have been more widely available since the beginning of the twenty-first century, as the recognition of trafficking as a global, regional, and national problem has increased. Because there is no uniform source of victim services for survivors, assistance for them has been set up primarily independently at the international, national, and local levels (Méndez, 2010). International organizations and conventions have established funds that are being used globally to assist survivors of trafficking, covering basic shelter, food, and clothing needs as well as victim compensation, relocation, legal assistance, and immigration documentation. Méndez (2010) mentions that the improved technology, communications, and transportation currently in the hands of the traffickers makes it imperative to provide victim services that are transnational and interconnected so as to provide the best possible services to survivors in this era of increased globalization.

While globalization, through the use of advanced technology, communications mediums, and transportation, has allowed traffickers to more effectively exploit people around the world, it has also made combating trafficking easier for

governments and NGOs. The same tools that have abetted traffickers are now being used by governments and NGOs; however, in order to increase the effectiveness of these tools, governments and NGOs must use one more tactic that has made human trafficking more successful: international collaboration (Surtees, 2008). The formal, successful human trafficker organizations that control large segments of international trafficking have long skirted the lines of jurisdictions in order to better serve their bottom lines (United Nations Office of Drugs and Crime, 2006). Combining globalization tools and transnational collaboration will make it possible for governments and NGOs to prevent trafficking, protect survivors, and prosecute traffickers.

Globalization and Religion

Abstract

This article examines the different ways that religion has been treated in the literature on globalization. Emphases in the literature tend to be on a global 'religious' function; on religious pluralism; on the religious dimension of local, ethnic, national, and civilizational identities; and on the way that transnational religious movements, religious organizations, and religious networks are able to go beyond and even ignore state and other local boundaries. Religion is a prime way of expressing both universality and particularity in global society. In contrast to the global capitalist economy, religions are more divergent than convergent; and yet, like culture and nation, religion is a social form to which all humans have access. Religions provide a way of multiplying ultimate narratives, and of doing difference in a situation where we all share the same place and time. Moreover, through the creation of diaspora communities, the amplification of readily accessible communication technologies, and the development of transnational organization, religions attain a more globalized presence. Globalization provides conditions for the multicentered reformation and reformulation of religious traditions, and for the creation of new religions whose existence is simultaneously global and local, tied to place and yet not tied to place.

Globalization, the historical process by which all the world's people come to live in a single social unit, brings with it religious changes as well. Prime among these is that globalization encourages religious pluralism such that religions identify themselves in relation to one another. Religions also become the objects of multiple centers of authority because of diasporas and transnational organization. In postmodern fashion, global religious pluralism creates a situation in which absolute visions end up living side by side and are engaging one another in highly diverse ways.

Globalization and Religion

Since the 1980s, the term globalization has taken on a certain currency in social scientific as well as in popular discourses. Its meaning in both these areas varies; but what unites economic, political, cultural, and even theological conceptions of globalization is the sense that, for better or worse, all people around the world live today in a single social unit much more than they ever have before. There is now and has been developing for some time a world society that serves as the encompassing social context of all more local social units. In this regard, most of the debates about globalization, whether scholarly or popular, have centered on the relation and even polarity between the global and the local. Roland Robertson (1992), a prime contributor to globalization debates since the 1980s, talks about the dialogical relation between the universal and the particular. The global context not only leads to a certain homogenization of cultures and social structures around the world, but also provides new conditions for constructing social and cultural difference. Global society, while single, is inherently pluralistic, not only permitting but even favoring a multitude of local and particular identities, both individual and collective. In that context, although this global society features great inequalities in power between what Immanuel Wallerstein (1979) calls core and peripheral regions, globalization is not just a matter of diffusion – say, of Western culture to the rest of the world; it is primarily the local appropriation of global models for such things as state, economy, or mass media in such a way that no region serves as the standard to which all others must conform. This is what Robertson and Zymunt Bauman (1998) call 'glocalization,' the global realized through the local.

The status of religion in debates about globalization has varied, to a significant extent according to academic discipline. Perspectives that see the development largely in economic terms, for instance as the increasing dominance of global capitalist institutions, tend to ignore religion almost entirely. However, an increasing number of approaches originating in the fields of international relations, political geography, and communication studies have, since the beginning of the twenty-first century, begun to pay attention to religion (Haynes, 2007; Calhoun et al., 2011). Yet it is still primarily the work of anthropologists, sociologists, and scholars of religion that accords religion a more visible place in the debate. Even here, however, analyses vary a great deal, for the most part depending on how the term 'religion' is understood. Two overlapping lines of variation appear to be central: the distinction between functional and substantive notions of what counts as religion, and whether one sees religion as an aspect of culture or as a differentiated and independent social domain.

A functional conception of religion regards as religion any social process that addresses certain problems, for instance the question of the ultimate meaning of life, or social integration and control. Here religion, or at least the religious, almost automatically becomes a necessary dimension in the formation of world society because problems of meaning or of self-description (integration) have to be addressed in any society, especially one as diverse as the global one. As examples under this heading, some authors have sought to analyze the emergence of a global culture that is the equivalent of a new global 'sacred canopy' (Meyer et al., 1997). One might even include a growing discussion about the development of a global 'civil society' under this heading (Rudolph and Piscatori, 1997; Juergensmeyer, 2005). In addition, a functional approach allows questions of national, regional, ethnic, or

civilizational identity in world society to take on religious character (Huntington, 1996; Robertson, 1992), and thus one will tend to see religion largely as an aspect of (global) culture. Substantive ideas of religion, by contrast, insist on the presence of identifiable and institutional sorts of activity that refer to a posited supernatural, transcendent reality. From this perspective, the relation of various specifically religious groups to globalization becomes the focus of attention, groups ranging from the Roman Catholic Church and Islamic organizations to Western Buddhist groups and Pentecostal movements (Martin, 2001; Learman, 2005; Rudolph and Piscatori, 1997). Such approaches also see religion as an independent domain of social activity and as more than an expression of something else, whether economics, politics, or culture (Beyer, 2006).

This variety in ideas about what counts as religion in the global context by itself already points to important aspects of the relation between globalization and religion. The fact that most of the literature that deals explicitly with globalization ignores religion or functionalizes it suggests that substantive or institutional forms are for these observers somewhere between irrelevant and antiglobal. One manifestation of this orientation is the great amount of attention that so-called fundamentalisms receive, and this, ironically, is very often from scholars who are quite positively oriented toward institutional or substantive religion. Thus, for example, the volumes issuing from Scott Appleby and Martin Marty's *Fundamentalism Project* (1991–95), although not directly about globalization, nevertheless assume globalizing processes; and they judge a wide variety of important religious movements all around the contemporary world as particularistic, and usually local reactions against them (cf. Juergensmeyer, 1993; Beyer, 1994). Among some of these authors, however, designating 'fundamentalisms' as, in effect, antiglobal movements parallels a positive attitude to the idea of a single world society, especially as manifest in the search for a specifically global ethos. In these cases, the search is on an explicitly religious basis, albeit not on the basis of a particular religion. What is somewhat ironic is that the resulting global ecumenical ethic (see esp. Küng, 1991) corresponds reasonably well to the intention of those who functionalize religion at the global level: that is, it avoids reference to a particular religion while addressing what it assumes to be the urgent and globally relevant religious task of providing ethical ideals and values that people all around the world can accept. In short, this sort of discussion seems to suggest that the distinction between functional and substantive conceptions of religion overlaps in a certain way those between the universal or global and the particular or local. Since these latter are principal organizing polarities in the entire globalization debate, it is best not to decide for one conception of religion or the other, but rather to consider the potential insights that flow from both.

Theoretical Perspectives

An excellent example of how a functionalized conception of religion can enter the globalization debate at the theoretical level is to be found in the work of John W. Meyer and his collaborators. In a 1997 article that clearly presents their basic outlook, they carry to the level of global society an analysis that the classical sociology of Max Weber and Emile Durkheim made for modern societies. For these scholars, the *world polity*, as they call it, is an extension of modern Western values and their corresponding rationalized structures to the rest of the world. Western religion had a critical role in bringing about this modernization and rationalization; but today the old religious elites have lost their power and have in any case also become believers in salvation through the pursuit of modern global values, especially progress (development) and equality. In their place, there is now a new 'religious' elite who are 'the professionals, researchers, scientists, and intellectuals who write secularized and unconditionally universalistic versions of the salvation story, along with the managers, legislators, and policymakers who believe the story fervently and pursue it relentlessly. This belief is worldwide and structures the organization of social life almost everywhere' (Meyer et al., 1997: 174). Meyer and his colleagues support the existence of this world polity by showing how the concrete policies of most countries around the world conform to its goals and values. In arguing in this fashion, however, they present a rather unitary and homogenizing picture that leaves room neither for the assertion of any meaningful particular or local variation nor, not coincidentally, for any role for institutional religion other than as futile reaction or powerless supporter.

A significantly more nuanced vision, as regards both the question of homogeneity vs heterogeneity and the possible role of institutional religion, is contained in the work of Roland Robertson. This author also emphasizes what he calls the 'globalization of societal modernity' (Robertson, 1991), which includes the sort of global religious function that Meyer et al. see. In addition, however, Robertson points much more positively to the proliferation of religious movements in the contemporary world, movements ranging from Latin American liberation theology and Küngian 'ecumenism' to Islamic 'fundamentalism,' Japanese Soka Gakkai, and the Sathya Sai Baba movement (Srinivas, 2010). His theoretical model makes room for these more institutional and substantive forms of religion, and not just as local defensive reactions against incorporation into the global system. Instead, Robertson allows that they can also be attempts to define the 'global-human' situation as a whole, and, *at the same time*, they can be ways of identifying a particular culture, region, or (in his terms) society in relation to the global whole and other subunits of it. The task of constructing such universalistic religious visions – whether functional or substantive – is always done on the basis of particular traditions, cultures, or movements. In consequence, the forms of institutional religion themselves change in the context of globalization, leading for instance to revisions of old traditions, syncretic or hybrid movements, and the rise of entirely new religions. For Robertson, then, the World Parliament of Religions, the Vishwa Hindu Parishad (World Hindu Organization), the Church of Scientology, a peripatetic pope or dalai lama, and Chinese Qi Gong groups are just as much aspects of globality and contributors to the shape of global society as are the aims and pronouncements of social scientists and technocrats. They all reflect and share a common social context, and one is not more modern or global than the other.

Religious Pluralism

From these theoretical starting points, one of the important questions that emerges concerns religious pluralism. Only with a radically functionalized concept of religion, such as that of the world polity school, can it appear possible for global society to share a single religious vision, a single worldview. All other conceptions point to the near impossibility of a hegemonic, global religion. Substantively speaking, contemporary global society shows no sign of moving in this direction. If anything, the opposite is the case: not only is there an increasing number of identifiable religions and religious traditions in the world, but also the variety of expressions within those religions is growing. Some sociologists of religion, such as Thomas Luckmann (1967), have long suggested that the increasingly dominant form of religious expression in today's global society is a highly individualized one that carries pluralism to the point where Luckmann can call it 'invisible religion.' Large institutionalized religions have been losing their authority and their social influence, but at the level of the individual, religious expression continues in myriad ways. These, however, are not publicly visible; they are private and in that sense invisible. Others do not go so far, but emphasize the degree to which even long-established institutional religions are manifesting themselves around the world in increasingly pluralistic fashion (Meister, 2011). Put somewhat differently, the question of religious pluralism is not simply one of how different religions, each one claiming an absolute vision, can live side by side in world society; it is also one regarding to what extent this society still favors authoritative institutions worthy of the name 'religion.' A partial answer is possible through a comparison of the idea of religion with those of culture and nation.

The model of global culture argues that, in the contemporary social world, the ideas of culture and nation serve as names for types of legitimate and fundamentally plural collective identities: cultures and nations, like individuals, have the right to equal existence. Within the context of homogenizing forces like global capitalism and mass media, one can assert one's difference and defend that difference in the name of one's culture or nation. Cultures and nations, like individuals, are legitimated agents or actors in global society: it is part of the world polity (of which Meyer et al. speak) that their right to 'self-determination' should be limited only by the right of other such identities to assert themselves in like fashion (Lechner, 1989). Religion is both a similar and different concept. On the one hand, religion in modern times has often formed part of cultural and national identities: it has very often helped to define them (Beyer, 2011). On the other hand, global culture also allows that religion is something independent of these other two notions. Religions are something to which people assumedly adhere voluntarily as individuals; and this may or may not flow from their cultural or national identities. Religions also enjoy the same 'protection' as cultures and nations; at least, such freedom of religion is an ideal expressed in most of the world's state constitutions (Richardson, 2004). Correspondingly, global cultural ideals regard religions, like cultures and nations, as inherently plural. Two seeming paradoxes emerge from this view. First, religious freedom is grounded not only in the individual's right to choose, but also in the right of the religious collectivity to exist and determine itself. Religious collectivities can therefore claim authority over their members, but only with the consent of these latter! Second, religions are particular and plural, and yet it is understood that they each offer a universal or cosmic vision, a total way of life. This holistic emphasis therefore includes the possibility of exclusivist religions, ones that deny the validity of all others. Thus, in true postmodern fashion, religions provide ways of multiplying ultimate narratives about how the world is, and they do this in such a way that each is regarded as of equal value, the choosing of one or the other being deemed a matter of preference, or upbringing, or culture. Ultimately, each is grounded only in the conviction of its adherents, and this in the knowledge that most others in global society have different convictions: even by the most generous estimates, the largest religion, Christianity, can claim far less than half of the world's population.

Religion in Postmodernity

The postmodern character of religion in the context of world society is manifest in other features as well. Embedded in the idea that religion is fundamentally plural are the questions of how religions distinguish themselves from one another, and what the difference is between religion and nonreligion. Neither question is susceptible to a simple and clear answer. The idea that there is a plurality of distinct religions is one that dates historically only from seventeenth-century Europe in the context of post-Reformation religious conflicts, and as European expansion brought its people into protracted contact with a much wider variety of other cultures, civilizations, and hence religious traditions. Which traditions emerged from this historical process as 'one of the religions' depended both on what Westerners observed as religions and on what non-Westerners were willing to style according to the implied model of a religion. Different and even diametrically opposite outcomes resulted. Thus, the elite carriers of 'Hinduism' took up the suggestion of Western observers and cooperated in reimagining South Asian religious traditions as somehow a single religion; whereas corresponding Chinese intelligentsia refused, in spite of Western observation, to reconstruct their Confucian thought and ritual traditions as a religion (Beyer, 2006). The contemporary list of (world) religions therefore has an inductive and even arbitrary character that cannot be reduced to abstract characteristics. Like nations and cultures, what comes to be seen as one of the religions depends in large part on how well the supposed members succeed in having others accept it as one.

The boundary between religion and nonreligion exhibits comparable ambiguities, the difficulty of deciding between functional and substantive ideas of religion being one example. At the core of this problem lies the notion that religion refers to an overarching view of the world and thus to a complete way of life; and yet religions are, in principle and in fact, plural. A prime symptom of this ambiguous status of religion in world society is that, over the past one and a half centuries, key representatives of almost all the so-called world religions have claimed that 'ours is not a religion.' Most often, protests of this

sort favor a broad functional conception of religion for their tradition, and they reject the sort of substantive one that limits religion to a special category of human action – say, one dealing only with interaction with gods or spirits. Similarly, opponents of various new religions have sought to exclude these from the category, in these cases so as to eliminate them from the range of legitimate religious choices. Such conflicts over categorization are, on occasion, ways of circumventing the global cultural value of 'freedom of religion,' justifying in these instances the obligatory adherence of everyone to the tenets and practices of a particular 'religion,' or preventing such adherence to another (Richardson, 2004). Thus, the category of religion in global culture allows a postmodern juxtaposition of absolute narratives without offering an overarching narrative to reconcile them.

Religious Authority, Transnational Organization, and Diaspora

Accompanying these various ambiguities regarding the category of religion and religions, the carrying out of institutional religion under conditions of globalization brings a number of other challenges and changes, especially with respect to questions of religious authenticity and authority. In any society, there are a limited number of ways through which conformity to authoritative religious traditions can come about. Thus, for example, in small-scale societies a relative lack of alternatives, and social structures centered on face-to-face interaction, could assure reasonable religious conformity. After the advent of writing and large-scale political empires, dedicated priesthoods or monastic orders, political state support, along with distinctions between elite and popular religiosity (e.g., religion vs superstition) could handle the problem according to hierarchical principles. Under conditions of globalization, neither relative social isolation nor hierarchical solutions are possible. Globalized communication media, from telephones and air travel to television and the internet, assure that religious social networks need not be limited to local interaction or particular places (Lyon, 2000). In fact, the existence of these possibilities positively encourages global or translocal religious networks and religious organizations. Moreover, the global cultural valuing of equality for both individuals and collectivities militates against the notion that the orthodoxy practiced or advocated by a certain group of religious professionals or adherents in a certain place should serve as the unquestioned standard for all others. Even in religions that have traditional centers of such authority (e.g., Rome for Roman Catholics, al-Azhar for Sunni Muslims, or Salt Lake City for Mormons), these centers have limited resources for enforcing their authority; and those that choose to ignore them can use the same techniques of individual religious freedom, (alternative) tradition, separate organization, and transnational networking to circumvent it. The only real exceptions are situations in which state power helps enforce religious authority; but in those cases, such as Iran, the state boundaries themselves set effective limits to such compulsion.

A prime illustration of the way that globalization encourages the multiplication of local centers of religious authenticity is the effect on religion of global migration and transnational religious networking and organization. Although the migration of people from one part of the world to others is a constant of world history, what is new under conditions of globalization is both the extent of the phenomenon and the fact that migrants leave one place for another far less definitively. The possibilities for maintaining communicative and even physical ties with the places of origin are far more developed, meaning that migrants are less dependent on their new contexts and can still influence the places that they have left. From a different angle, the difference between migrants and nonmigrants is not as great as it used to be, just as the difference between travel and tourism vs migration is not as clear. And the chief source of this new situation is the much greater and more rapid communicative links that now exist throughout the world.

Among the consequences for religion of migration and enhanced transnational or translocal linkages, two are of the greatest potential significance. The first is that, as migrants from a particular religion settle in different parts of the world outside of the traditional 'heartlands,' these diaspora communities will develop religious variations that respond to their new locations, and may furthermore re-export these to their places of origin as authentic and authoritative versions. Thus, for example, the temples that Hindu migrants typically set up in diaspora communities of Europe and North America often allow the worship of a range of gods and goddesses in the Hindu pantheon, unlike in India where temples are usually dedicated to one deity only. The diasporic 'one-stop supermarket' temple is primarily a response to the fact that Hindus from different parts of India migrate to the same places and that these communities do not have the resources to build temples for each subgroup. In spite of these strategic origins of the variation, however, the model is being transferred back to India, providing another authentic way of 'doing' this religion (cf. Waghorne, 2004). Similar analyses could be made for Muslim, Christian, Buddhist, or other migrants.

The second major consequence for religion is related but also in a sense opposite. It consists in the possibility of tying together disparate versions of a religion across the globe, expressly in spite of the difference in local variations. The Roman Catholic Church is perhaps the prime example of a religious organization that has taken great advantage of this possibility. In many ways, it is the 'same' no matter where one goes in the world, and yet local variations are not thereby suppressed or excluded. The links among the world's Islamic populations have also strengthened significantly in this context, such that one can speak of a 'global Islam' in spite of the significant variations in the practice of this religion all around the globe (see Levitt, 1998; Roy, 2004). Another very illustrative example is global Christian Pentecostalism. Here, the concrete ways of doing Pentecostal Christianity vary enormously when one compares places like South America, North America, Africa, Korea, and elsewhere in Asia. Yet transnational linkages in such forms as common publications, regular world conferences, connections among professionals, and migration encourage a consciousness in most Pentecostals of being part of the same worldwide religious movement, in spite of the differences among them (see Poewe, 1994).

Conclusion

What this article demonstrates is that globalization creates and enhances conditions in which religion can become more pluralistic and yet at the same time more unified. The local and the global in religion, the universal and the particular, are not opposite poles between which religious forms oscillate. Rather, local religion can now increasingly only be done with reference to the global context, especially in the awareness of religious pluralism. And global religious forms expressly include and are the expression of local manifestations. Global society does not present the choice between antiglobal, perhaps 'fundamentalist' resistance and proglobal, liberal accommodation. Instead, it recreates the conditions under which religions form and operate in relation to one another (Corten and Marshall-Fratani, 2001).

Globalization and Transnational Corporations

Abstract

This article first reviews debates that stress the contrasting interpretations of globalization existing at the social, political, and economic levels. Globalization is defined in terms of the combined processes of acceleration of time and compression of social space. The development of transnational corporations (TNCs) since the 1960s reveals that these organizations, that operate globally and do not necessarily identify with a particular country, play an increasingly important role in the global economy, politics, and society. This article reviews the primary interpretations of the position and role of TNCs under globalization.

Globalization

Definitions and the Debates

The concept of globalization has been employed to define processes at the social, political, and economic levels. Socially, it has been interpreted as a complex phenomenon that molds distant groups into unified networks, allows enhanced communication, promotes the exchange of ideas and experiences, fosters understanding and bringing people closer together (Croucher, 2004; Hopper, 2007; Jagdish, 2004). It has also been viewed as an entity that increases interdependence, mutual exchange awareness, and respect and fortifies society's cohesiveness (Friedman, 2005; Guillen, 2001). Globalization's greater circulation of capital, labor, and products has been heralded as one of the primary conditions for social growth (Wolf, 2004). These positive views have been countered by interpretations that analyze globalization as a phenomenon that engenders the exploitation and oppression of local groups and cultures, eliminates differences, represses identity, and instigates radical resistance and opposition (Barber, 1995; Giddens, 2000; Hosseini, 2009; Ritzer, 2008). It has been further regarded as a process that enhances the centrifugal power of capitalism, dismembers communities, and undermines the stability of society (Amoore, 2005; Harvey, 2006; Giddens, 2000).

Politically, globalization has been analyzed as a deterrent to unilateralism and a tool to enhance cooperation among people and nations. While the United States remains the 'benign hegemon' of the world, the working of the global system is based on, and nurtures, a greater participation of all people in governance (Friedman, 2000). This view is opposed by concerns about the reduced power of the nation-state and the limited ability of people to be represented in political debates and decision making. The crisis of political representation (the declining connection between the rulers and the ruled), and the growing inability of democratic political institutions to control the actions of global corporations and actors have often been mentioned among the most distinctive outcomes of globalization (Boggs, 2000; Wettstein, 2009).

Economically, globalization has been described as a condition for growth and a tool for the elimination of socioeconomic inequality. Because of globalization, income is now distributed more justly and the idea that one or few nations can dominate other nations is considered obsolete. The emergence of a global ruling class, it is argued, promotes just development (Becker and Sklar, 1999; Firebaugh and Goesling, 2004). Opponents of globalization have indicated that globalization is a class project that increases the exploitation of the lower classes and the global South (Harvey, 2005, 2010; Robinson, 2004). It has been also defined as the outcome of the growth of monopoly capital that engenders crises and stagnation (Bellamy Foster and McChesney, 2012). Others contend that the growth of transnational corporations (TNCs) and the declining power of political and economic institutions (i.e., the nation-state, unions, and social movements) resulted in the concentration of wealth in the hands to the top 1% of the world population and the worsening of the socioeconomic conditions of the rest of society (Milanovic, 2011; Stiglitz, 2003; Volscho and Kelly, 2012).

While contrasting interpretations characterize the debate on globalization, there is convergence on the definition of this phenomenon. It refers to the acceleration of the time and the compression of space within which social relations take place (Harvey, 2010; Bonanno and Cavalcanti, 2011). In other words, globalization means that the social world is 'smaller' and people 'move about it in a much faster way than before.' Viewed as the acceleration of social time and the compression of the social space, globalization does not appear to be a novel process. In effect, these have been constant characteristics of the development of capitalism. As indicated by classical social theorists – such as Karl Marx and Max Weber – the advent of capitalism mandates a constant acceleration of time and compression of space. The novel dimension of current globalization is that time acceleration and the compression of space occur in a quantitatively and qualitatively enhanced manner than in the past (Robinson, 2004).

At the spatial level, the establishment of capitalism meant that the feudal regional space was reorganized in favor of the creation of a greater (national) capitalist space and its political representation of the nation-state. Marx (Marx and Engels 1998 [1848]: pp. 39–41), for instance, underscores the historical importance of the creation of a 'national space' in which interdependent markets, business organizations, and labor networks are established, organized, and controlled and where commodity production and consumption are organized and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64132-6

executed more efficiently and rapidly. At the level of time, the increased velocity of the turnover time of capital and overall efficiency in the capitalist structure of accumulation were paramount for economic growth. Nation-states employed their powers to establish, organize, and control national markets and to assist their bourgeoisies in expanding the scope and size of the economy. Simultaneously, bourgeoisies expanded their space of action, and organized and controlled the forces of production contained within it, and, most importantly, the use of labor. Marx saw homogenization and standardization of production processes and their organization under national laws, interests, policies, and practices, via the state to be primary objectives of the capitalist class. Weber (1963: pp. 166–68) viewed the standardization of time and space as a new moral dimension that propelled the growth of capitalism.

Yet, classical social theorists recognized that capitalism was never exclusively domestic and that, in fact, it is global in nature. In the case of Marx, he stressed emphatically that capitalism's dynamic nature generates business activities far beyond the nation-state's organized and increasingly homogenous spatial dimension. He argued that capital mobility, under modern industry, transcends the nation and with that the regulatory and controlling dimensions through which the nation-state embeds the economy culturally and institutionally. Marx held that capitalism's tendency to expand would lead to a global capitalist system. It must create and recreate new spaces to continue the search for profit. The bourgeoisie's need to reshape space to fit the requirements of capital accumulation, organize its factors of production and, above all, to reproduce and control labor was, for Marx, a fundamental component of capitalism. Capital accumulation requires economic and political concentrations that are manifested through the organization and regulation of the use of the forces of production. Simultaneously, the regulation of the forces of production requires the existence of forms of social interdependence – such as that between capitalists and workers – that are codified in the spatial and temporal conditions associated with the nation. As these conditions are eroded and capital mobility transcends the nation-state, established forms of interdependence are destroyed displaying the contradictory and unsustainable dimension of capitalism.

The Origins of the Term Globalization and Debates in the Late Twentieth Century

Despite these classical insights into the development of a global economy and society, the term globalization was rarely used for most of the twentieth century. In effect, its origins and first use are not very clear. There are unconfirmed claims that references to global socioeconomic processes were made in the first portion of the twentieth century. However, it was only in 1951 that the Merriam-Webster dictionary of the English language officially acknowledged the word globalization. In academic circles, the term gained some recognition in the 1970s through some publications that discussed the growth of multinational corporations (MNCs) (Barnet and Muller, 1976; Hymer, 1971). In 1972, the political scientist Fuad Ajami employed the term globalization to stress the characteristics of the expansion of corporations at the global level. In the early 1980s, Theodore Levitt published the article 'The Globalization of Markets' in the Harvard Business Review (Levitt, 1983). Disregarding classical debates, Levitt argued that the world entered a new era in which national differences in consumer preferences had become largely irrelevant. Changes at the technological and social levels allowed corporations to market their products worldwide in ways that were impossible before. The essence of Levitt's argument was that a set of new and qualitatively different factors enhanced the ability of companies to conduct business globally. After this and similar works published in the 1980s, the term globalization gained worldwide popularity.

As the debate evolved in the 1980s and 1990s, it was characterized by three camps. The first referred to the once dominant Modernization School. Its key argument of the world development is characterized by the independent and autonomous growth of nations (Parsons, 1971; Rostow, 1960). Such views were criticized for blaming poor countries for their conditions, justifying the unequal redistribution of resources and power, disregarding the relationship between development and underdevelopment, and, ultimately, ignoring the historical conditions that shape development. In its ahistorical formulation of growth, modernization theory proposed a view in which each country would develop by adopting the culture and institutions of the United States. This process of cultural and economic modernization or Americanization (Parsons, 1971) would be reached through stages that would be achieved according to each country's own ability to mobilize the necessary resources to grow (Rostow, 1960).

Objections raised by Marxian structuralists were particularly strong. This camp consisted of two major subgroups. The first included the world system school led by Immanuel Wallerstein (1974; 1980; 2005) while the second referred to the regulationist school (Aglietta, 1979; Lipietz, 1987, 1992). The world system school borrowed from the Longue Duree School (The Longue Duree group refers to that group of scholars that were originally associated with the French journal *Annales d'histoirie économique et sociale*. First popularized in the 1930s and 1940 by the work of Marc Bloch and Lucien Febvre, and later in the post–World War II decades by that of Fernand Braudel, this group's historiography was centered on the importance of the evolution of long-term historical conditions (from this the name Longue Duree or long term) and the view that contemporary socioeconomic phenomena find their roots and explanations in established historical trends. Wallesterin, along with other important representatives of the world system school such as Giovanni Arrighi, was associated with the Braudel Center at the State University of New York, Binghamton.) and emphasized the long-term evolution of social relations. For Wallerstein, development could be understood only by analyzing the emergence of capitalism in Europe and its evolution. This evolution, he contended, culminated in a 'world system' in which all nations were connected together in patterns of growth but also underdevelopment. Rejecting the assumption that the growth of each nation evolves following indigenously based stages and strategies of development, world system theorists demonstrated that the development of advanced societies (core countries) was the result of processes of underdevelopment of countries in the periphery (underdeveloped countries) and semiperiphery (less developed countries). Under world capitalism, the socioeconomic growth of

core nations was the direct outcome of concomitant processes of underdevelopment of countries of the world periphery and semiperiphery.

At this stage of the debate, the contribution of world system theory was relevant for at least two reasons. First, it proposed a view in which the global system was understood as a process that initiated with the growth of capitalism. Accordingly, and following Marx's classical analysis, world system theorists rejected the thesis that attributed the genesis of globalization to recent events and insisted on the long-term dimension of the phenomenon. Second, world system theory reaffirmed the centrality of the nation-state in contemporary capitalism. While they stressed the historical nature of the nation-state – the nation-state is only one of the historical forms of the state – they also viewed the world system as a system among nations, an international system. In this respect, world system theorists remained skeptical of statements that associated globalization with the crisis of the nation-state.

World system theorists' skepticism about the novelty represented by globalization remained. And statements about this concept's inadequacy were re-proposed periodically. Wallerstein (2000), for instance, has frequently and overtly argued that globalization is not a new phenomenon. Christopher Chase-Dunn (1998) contended that "Most discussions of globalization assume that, however defined, it is a fairly recent phenomenon … [I]f we take a long-term view of the structural constants, cyclical processes, and secular trends that have operated in the Europe-centered system for several centuries we can understand that there have been no recent major transformations in the developmental logic of the world-system" (Chase-Dunn, 1998: ix).

Exemplifying the reaction to this position, Robinson (2004) argues that there are quantitative and qualitative differences between globalization and previous periods of capitalist development. Accordingly, it is misleading to argue that globalization is simply the continuation of trends established in the past. From a quantitative point of view, Robinson maintains that trade is much larger under globalization than in other historical periods and this is the case also for the scale of capital flows, and the level of information and communication technology. He also stresses the differences associated with the global presence of TNCs and a transnational labor force. Qualitatively, Robinson underscores that globalization "has entailed the fragmentation and decentralization of complex production chains and the worldwide dispersal and functional integration of the different segments of these chains … In this way globalization is unifying the world into a single mode of production and a single global system and bringing about the integration of different countries and regions into a new global economy" (2004: p. 15). He concludes that because of these changes the nation-state has lost the central role that it played for most of the twentieth century.

Members of the regulationist school maintained that each era of capitalism was defined by a 'regime of accumulation' and a 'mode of regulation.' The concept of regime of accumulation refers to the system of wage relations that defines a particular era of capitalism. Mode of regulation indicates the social norms that govern each regime of accumulation. In the 1980s, regulationists concentrated their efforts on the analysis of the end of Fordism and the emergence of a new and post-Fordism regime of accumulation. At the time, post-Fordism was used widely to refer to conditions that latter would be associated with globalization.

According to the regulationists, Fordism indicated the 'regulated capitalism' that characterized most of the twentieth century. Introduced by the Italian philosopher Antonio Gramsci (1971) to define the advanced Taylorist capitalism of the 1930s, it was re-proposed by the regulationists to refer to the combination of Keynesian political economy and state intervention at the social level that characterized the development of advanced Western societies in the post–World War II decades. The crisis of Fordism, they contended, was the result of the so-called rigidities of this regime of accumulation. Also theorized from a number of different perspectives (see O'Connor, 1974; Habermas, 1975), the concept of rigidities referred primarily to the fiscal and ideological dimensions of Fordism. At the fiscal level, the cost of maintaining state intervention became too high. The combination of an increased demand for state-sponsored services and the world economic crisis of the early 1970s prevented many nation-states from continuing their support of corporate activities at previous levels. State attempts to increase tax and introduce more regulations motivated corporations to export profit and bypass state requests. The result was a fiscal crisis of the nation-state. Simultaneously and at the ideological level, the inability of nation-states to address many of the existing social issues discredited the political elites and their ideologies. This legitimation crisis engendered widespread calls for changes in the administration of society and the economy. The regulationists viewed these changes as indications of the emergence of a new global regime that they called post-Fordism.

Postmodernity was the third major camp that characterized the debate on development and globalization in the 1980s and 1990s. Dwelling on poststructuralist contributions (Foucault, 1969, 1975; Derrida, 1978), postmodern theorists (e.g., Baudrillard, 1983, Laclau and Mouffe, 1985, 1987) argued that the issue of global development could not be adequately addressed employing 'grand narratives.' By grand narratives, they referred to holistic explanations that could be applied across time and space. In their critique, they maintained that the complexity of human existence could not be explained by modern theories and their assumption of universalism. Similarly, development could not be understood by using these modern theories. Denouncing the oppressive character of grand narratives, postmodernists maintained that the elimination of class inequality would not necessarily address other forms of oppression such as gender, race, and ethnic dominations. Furthermore, liberation strategies that spoke for the disenfranchised often silenced the very voices they claimed to support. In contemporary society, theories of development and liberation were transformed in theories of oppression. Their critique of left leaning and socialist theories was often more strident than those coming from the far right. Their argument centered on the historical failure of socialist projects and the 'exclusion' and 'oppression' of many groups that these theories and practices engendered. The global society, they contended, requires the acknowledgment of the existence of a plurality of voices and patterns of action as repression emerges from all sides of the political spectrum.

Globalization and TNCs

In the first two decades of the twenty-first century, the debate on globalization expanded significantly and included contributions on the growth of TNCs. In these contributions, TNCs are defined as enterprises that operate globally and have virtually severed connections with their home nation-states. They act disregarding the interests and well-being of their home countries and governments. They are different from MNCs that are enterprises that operate in more than one country through branches and subsidiaries. Their national origins are known and recognized as they are identified with, and claim membership in, a particular nation-state. They also differ from domestic corporations – enterprises that operate predominantly within one single nation. In relevant literature, the difference between MNCs and transnational or global corporations is often downplayed. In effect, the two terms are often used interchangeably. Simultaneously, it has been underscored that many MNCs have evolved into TNCs in recent decades.

The transformation of MNCs into TNCs has been associated with the growth and crisis of Fordism. During the Fordist twentieth century, MNCs strengthened the *mother–daughter* industrial system (Dunning, 1993). In this system, a *mother* company with headquarters and operations in the metropolitan homeland opened *daughter* subsidiaries overseas. These subsidiaries were directly controlled by, and managed from, the home headquarters and, therefore, operated with a highly restricted autonomy. As the twentieth century unfolded, MNCs expanded counting on the active military, political, and economic assistance of their home nation-states. Additionally, MNC's ownership and management, while including an international presence, remained largely in the hands of citizens of the company's home country, a situation that further legitimized the intervention of home governments in host countries. In return, host countries benefited from the repatriation of profit and the associated tax revenue, domestic investment and the creation of local jobs that contributed to social stability and economic growth.

The beneficial association between MNCs and the United States and other major nation-states reached a point of crisis in the late 1960s and 1970s. As the United States was increasingly asked to assist and protect MNCs, the search for more lucrative markets – including commodity and financial markets – and new cost-saving operations pushed MNCs to repatriate profits at an increasingly lower rate. While foreign direct investment (FDI) increased, this move signified less revenue for the home state and the concomitant escalation of fiscal pressure. In the United States, the declining rate of repatriation of profit exacerbated the fiscal crisis of the American state. The success of the postwar Fordist system mandated an expanded welfare state and social services that were supported through state expenditures and taxation. Corporations contributed to Fordism by maintaining high wages and salaries that sustained mass consumption and provided popular legitimacy to it. Internationally, the American government's actions to maintain the Pax Americana also became increasingly costly monetarily as well as politically. The Vietnam War crisis symbolized the high monetary and political costs associated with US control of the world economy and politics.

Responding to this new domestic and, and above all, international economic situation, first the United States, and later European, corporations expanded their foreign affiliates and FDI. Some developing countries counteracted through the expropriation of corporate assets and the implementation of import substitution strategies that favored local companies. Fueled by the negative economic consequences of the oil crisis, the loss of legitimacy of the modernization project and a move to the political left by many governments, more host countries overtly antagonized MNCs' presence on their territories. In order to overcome what they perceived as mounting adverse conditions, MNCs adopted novel means to reignite profitability. They began to decouple their presence overseas with the interests of the home countries. They began global searches for convenient production sites featuring favorable political contexts, support for deregulation, privatization of once publically controlled enterprises and resources, and open markets. They searched for locations in which national and regional governments adopting neoliberal policies allowed the creation of production networks that transcended the classical mother–daughter system. In essence, the corporate response to the crisis of Fordism consisted in the 'transnationalization' of their operations. Decentralization of production, the creation of production and distribution networks, and the global mobility of profit and investment defined the new TNCs (Robinson, 2004; Bonanno and Constance, 2008).

TNCs' moves were entwined with changes in the posture of many nation-states – and primarily the United States – that embraced neoliberal ideology and policies. Framed as an effective manner to attract fleeing corporate investment, nation-states adopted globally oriented macro-organizational strategies that shifted emphasis away from socially oriented goals (i.e., social stability, equitable socioeconomic growth, and welfare spending) to profit enhancing objectives. In this context, the allocation of FDI became increasingly linked to the 'regulatory and policy instruments' employed by nation-states and the existence of supportive economic policies. This trend was a common feature of national economic policies worldwide during the final years of the twentieth century. The neoliberal deregulation of markers eroded the long-standing association between corporations and home countries as TNCs began to look for the maximization of profit at the global level, paid increasingly less attention to the home country's domestic problems, and lack of corporate accountability emerged as a new 'social problem.' TNCs increase in FDI, for instance, while creating fresh opportunities for corporate profit, was one of the factors behind the *deindustrialization* process and the loss of many well-paid and stable jobs in many home countries.

In pertinent debates, the relationship of TNCs and the nation-state is discussed in contrasting terms. Extreme readings of this process (see Ohmae, 1995) portray TNCs as entities that have cut their 'home nation' attachments and operate as almost exclusively stateless global actors. Because of TNCs' power and ability to freely move about the globe, Ohmae and likeminded scholars argue that the nation-state has lost most, if not all, of its ability to control and regulate economic and social matters as it did in previous eras of capitalism. Framed as the ability of TNCs to 'bypass' state requirements, the crisis of the state has been identified as one of the most distinctive features of globalization (e.g., Ohmae, 1995; Constance and Heffernan,

1991). Reacting against this position, some authors, such as Arrighi (2005, 1998), Chase-Dunn (1998), and Hirst and Thompson (1996), contend that the nation-state continues to remain the centerpiece of capitalist development and an entity needed by corporations operating domestically and abroad. Corporations, therefore, maintain their links with nation-states even though conflict and divergence of interests may arise. According to this view, capitalism continues to be characterized by international social relations or relations among nations. It remains centered on the evolution of the nation-state and its capacity to forge a more or less unified national identity and culture while promoting and controlling the flows of resources and processes necessary for the development of the economy domestically and internationally. For Paul Hirst and Graham Thompson (1996), for instance, true TNCs do not exist so the purported socioeconomic changes that resulted in the creation of TNCs are unsubstantiated. They maintain that most corporations are still national as they are still connected to their countries of origin in significant ways regardless of their international activities. Additionally, data do not indicate the existence of trends toward the emergence of truly global corporations. In effect the examination of FDI reveals that it is generated by companies located in North America, Europe, or Japan. Hirst and Thompson further maintain that while the postwar system that regulated capitalism has exhausted its role, a new system of regulation has been set in place. This new mechanism allows the three superpowers (the United States, the European Union, and Japan) to govern the world and ensure adequate levels of socioeconomic stability.

According to other scholars (Dicken, 1998; Harvey, 2010, 2005; Robinson, 2004; Sklair, 2001), the recent evolution of the economy and society has brought about a qualitatively different set of conditions for the accumulation of capital of which the growth of TNCs is among the most relevant. The distancing between TNCs and their home nation-states alters the historically built connection between these two entities. Corporations increasingly bypass home state requirements and requests while they strategically forge associations with other nation-states and regional or continental groups of nation-states (Bonanno and Constance, 2008). Because of these changes, the modus operandi of TNCs is different from the historical role played by MNCs throughout most of the twentieth century. These scholars also stress that TNCs play an active role in the underdevelopment of many less advanced regions and nations of the world. The soaring corporate power, they argue, has negative consequences for the economy and society as economic inequality increases and the unchecked actions of corporations are destabilizing (Krugman, 2007). They identify TNCs as active contributors to the mechanisms that allow the transfer of wealth from periphery to core countries. Furthermore, they question these corporations' social and political practices. TNCs have been often identified as 'undesirable citizens' that contaminate the democratic institutions and political climates of host countries and engender unwanted social consequences such as environmental pollution, labor exploitation, political violence, physical abuse, and death. They contend that the power of TNCs reduces the level of democracy and prevents national and regional constituencies from participating in decision making processes (i.e., Boggs, 2000).

Scholars who support neoliberal positions express much more sympathetic views of the TNCs' actions. They maintain that those who oppose corporate actions and presence in less developed regions do not recognize the benefits that expanded business opportunities generate for these societies and the fact that they would suffer many more negative economic consequences in the absence of corporate investment and business activities. Because of their visibility, TNCs obey the law in much greater extent than smaller companies. However, also because of their visibility, they are often attacked by a variety of opponents, including unsympathetic nation-states. Advocates of this position hold that TNCs, to defend themselves, are sometimes forced to take actions that cause negative social and political consequences in the host country. However, they also argue that the claim that TNCs coerce nation-states to accommodate their interests through the use of illegal means is 'greatly exaggerated.' They contend that TNCs generate far more positive socioeconomic consequences to the communities where they operate than the negative outcomes often reported in scientific and popular venues (Rubner, 1990; Firebaugh and Goesling, 2004).

According to these accounts, the economic decline of the United States and the concomitant growth of Europe and Japan, as new world powers experienced since the 1960s, affected the regulation and coordination of world affairs based on the nation-state system. In this context, corporations could no longer depend on the United States to maintain global order and on nation-states' actions to support corporate interests domestically and internationally. The global development of anticorporate sentiments in advanced countries produced a public mood of indifference to the adverse treatments and conditions that corporations experience abroad. This situation affected advanced countries' governments that grew increasingly unwilling to intervene. Additionally, the growth of anticorporate movements – such as the environmental and labor movements – placed public opinion in direct opposition to corporate interests. Some of the consequences of this situation are that TNCs' objectives are, now more than ever, diverging from those of nation-states. Because of this emerging hostility, TNCs are often forced to operate to counter nation-states' behaviors that are damaging to their interests. This posture does not only pertain to the company itself, but also to the behavior of managers.

The view that TNCs are better world citizens than otherwise believed and that they act to defend their legitimate interests in hostile political environments is also shared by scholars who identify with the political left. Gavin Kitching (2001), for instance, articulates a 'qualified defense' of TNCs (2001: p. 42) whereby he contends that not only the number of TNCs (or 'supranationals' as he calls them) engaged in behavior that causes negative social and economic consequences in host countries is greatly exaggerated, but that this behavior is the result of structural conditions that ultimately dictate TNCs' actions. Supranationals, he argues, are far better employers than many 'local' companies as they provide better wages, working conditions, and obey local laws. One of the reasons for this behavior is that TNCs can afford to be more 'generous' than local companies. In effect, the cost of labor in developing regions is very much cheaper than in developed countries that it is still a bargain for TNCs to pay high 'local' wages. Also,

because TNCs lack local political legitimacy, they need to be on their best behavior and appear as model employers to win over the trust of host governments (Kitching, 2001: p. 43). Yet, it is the absence of a global regulatory entity (i.e., the absence of a global state that would compensate for the declining hegemony and capacity to control world industrial and political relations of the United States) that constitutes the most important structural reason behind the often publicized 'negative' corporate behavior. Due to the lack of this global regulatory entity and the consequent political and economic instability and uncertainty, TNCs tend to give preference to short-term goals (profit) over a more balanced and constructive local presence. It is the structural gap between a world economy and the local polity that ultimately affects TNCs' behavior. Corporations, he concludes, cannot change this situation as it can be altered only at the political level through the creation of a world political system that could regulate the economy and provide the basic conditions for social stability. For Kitching, the spread of TNCs presence worldwide creates new opportunities for developing regions and workers. While jobs may be 'lost' in developed regions with the consequent protest by local unions and left-leaning political groups, new jobs are created in less developed regions. He contends that if one job created is equal to one job lost, the fact that jobs reappear in the less developed South is a positive sign in the struggle to reduce socioeconomic inequality worldwide. He dismisses as unsubstantiated the objection that the creation of new jobs in less developed regions often does not translate into the actual lifting of workers out of the subsistence level. He contends that currency instability along with government's attempts to maintain export competitiveness depress wages and do not eliminate the threat of market withdrawal through plant relocations.

The growing power of TNCs has characterized globalization since its outset and has been a persistent theme in pertinent literature. In current debates, there is consensus that TNCs will continue to be powerful actors in the economy and society. Disagreement, however, exists in regard to (1) the extent to which TNCs have the same level of power that research attributed to them a decade ago and (2) the consequences generated by the application of this power. According to one camp (i.e., Busse, 2004; Macleod and Lewis, 2004), TNCs will continue to be powerful actors and their ability to control nation-states, social groups, and economic policies will continue unabated. A second camp consists of authors who argue that the power of TNCs is not as absolute as some analyses would contend. While TNCs remain powerful actors in the global context, their power is resisted at various levels. Resistance emerges from a number of actors including nation-states, local groups, and social movements. A number of studies have underscored the role that consumers play in shaping TNCs' actions (Humphery, 1998; Marsden, 2003; Wright and Midderndorf, 2007). It is argued that consumers' behavior is increasingly affected by social values – such as the protection of the environment; health concerns; the protection of workers and communities in less developed areas; fair processes of trade – rather than price. Accordingly, as consumers' social consciousness affects demand, it also affects the behavior of corporations and their power. It is further argued that the power of TNCs is also limited by internal organizational constraints and contradictions (Bonanno and Constance, 2008). Because they compete with other corporations and have relatively limited organizational strength given the scope of their actions, TNCs encounter difficulties in exercising power at the global level.

Globalization and World Culture

John Boli and Frank J Lechner, Emory University, Atlanta, GA, USA

Abstract

This article explores the origins, development, structure, and impact of world culture in relation to globalization over the past two centuries. It discusses the complex and largely rationalized content of world culture and the rise and proliferation of organizations that generate, debate, and propagate world culture, particularly international nongovernmental organizations. It describes world-cultural processes that promote homogenization and heterogeneity at the global, national, and local level, and the consequences for national identity of world-spanning cultural development. The article concludes with a discussion of the role and significance of religions and religiosity in a globalized world.

Globalization and the Construction of World Culture

Globalization entails the spread of conceptions of the world as a single entity – for example, a single and highly complex society, market, polity, technical system, or culture (Robertson, 1992). At a more concrete level, globalization entails the many organizations, associations, and social movements of global orientation that structure worldwide flows of goods and services, people, knowledge, religions, ideologies, and much more. World culture refers to the complex array of foundational assumptions, forms of knowledge, and prescriptions for action that underlie globalized flows, organizations, and movements (Lechner and Boli, 2005). Its webs of significance span the globe, providing knowledge, rules, policy prescriptions, conceptions of world society, purposes of human action, and models and methods of structuring social life that are assumed to have worldwide significance or applicability.

Some examples of the content of world culture will help convey its meaning. The rules of chess are elements of world culture; the game is defined by a standard set of procedures that are deemed valid everywhere, and departures from those rules are considered nonsensical. The principles of physics are world-cultural, assumed to apply at every point on the globe and even beyond. Human rights, as codified in the Universal Declaration of Human Rights and its associated conventions, are couched in world-spanning terms, applying to all humans in all countries. The technical standards (ISO/IEC 4909:2006) for the dimensions, thickness, tensile strength, and other properties of financial transaction cards produced by ISO, the International Organization for Standardization, are presumed to be useful and technically rational for any maker or issuer of such cards. Other examples of world culture include the 'model subcontract' produced by the International Chamber of Commerce, a template for international business relations; the pathologies identified in the World Health Organization's *International Statistical Classification of Diseases and Related Health Problems*; and the Six Sigma management methodology that is promoted worldwide as a means of improving business performance. What these examples have in common, despite their highly disparate social fields, is the presumed universality that is associated with them. They are elements of the culture of the globalized world, their proponents seek to spread them globally, and they are presumed to have meaning or value wherever they may be implemented.

World-cultural elements are not necessarily embraced or accepted universally, however. Like the cultures and subcultures of national societies, world culture is replete with competing cultural elements and contradictory principles. For example, democratic governance principles are strongly embedded in world culture, but many varieties of democracy are available and some segments of world society favor nondemocratic regime forms. The major world religions are elements of world culture, but they disagree sharply on such fundamental issues as the existence and nature of divinity, the purposes of life, and the fate of the soul. Some elements of world culture are hotly debated, such as the International Panel on Climate Change's claim that human action contributes to global warming and the neo-liberal economic claim that free markets are the best means of raising living standards. Hence, while many elements of world culture are largely taken for granted, many other elements are contentious, contradictory, or controversial.

World culture is the product of many forms of social activity and many types of social actors, reaching far back in human history. In its contemporary form, world culture began to coalesce in the second half of the nineteenth century. We can trace its emergence through the rise of international nongovernmental organizations (INGOs), which are the key structural form through which world culture is expressed (Boli and Thomas, 1999). The earliest of these voluntaristic, purposive, specialized associations emerged in the first half of the nineteenth century, but it was not until the 1870s that their numbers began to grow rapidly. It was also at this time that the range of human activities they address broadened widely, eventually covering almost every imaginable social field. INGOs are especially important with respect to world culture because they operate explicitly at the transnational level and much of their work deals directly with world-cultural principles and prescriptions. Science INGOs develop and propagate scientific principles; professional INGOs propagate knowledge and ethical principles relevant to their respective professions; sports INGOs codify and promote 'rules of the game' and principles of sportsmanship; and education INGOs promote teaching methods, curricular development plans, and policies to protect teacher autonomy in the classroom. Across the

board, these principles and norms are couched in universalistic terms, and universalism was strikingly evident in the outlook and work of the vast majority of INGOs that formed before the mid-twentieth century. These bodies welcomed members from all parts of the world and presumed that their knowledge, ethics, and prescriptions were applicable all over the world.

Since World War II, world-cultural structuration has become more complex; a layered transnationalism has appeared as regional organizations have proliferated. By one count, roughly half of the transnational organizations founded since 1950 have been regional in scope, activating a variety of types of regions: geographic (European, Latin American, Asian), linguistic (francophone, hispanophone) religious (Islamic, Christian, Jewish), climatic and vegetational (tropical areas, rain forest zones), and so on. This regional intensification has occurred within the larger global cultural frame, and it characterizes the internal structure of global organizations as well. For example, the World Health Organization (founded in 1948) eventually developed regional bodies for each major part of the world (the Americas, Africa Southeast Asia, etc.), while ISO helped with the establishment of regional standardization bodies (e.g., the European Committee for Standardization, the Pacific Area Standards Congress) that coordinate their activities with those of the larger global organization. The same process is common in global corporations. For example, CNNI (Cable News Network International) began as a unitary organization bringing a standardized English-language product to televisions around the world, but it eventually established numerous regional centers producing local-language broadcasting adapted to specific target audiences but tied closely to CNNI's overarching global operation.

An important mechanism for the spread of world culture in the post-war period was the rapid decolonization that yielded more than a hundred new states covering a large portion of the world's land mass. As colonies, these societies had been only weakly integrated into world culture, however deeply they may have been integrated into the world economy. Most new states have eagerly joined large numbers of intergovernmental organizations (IGOs), interacting with older states as they learn about and debate world-cultural principles and prescriptions. Citizens of the new countries became avid joiners of INGOs, expanding the range of their memberships much faster than that of citizens of older countries. Thus, political independence opened the door to much greater participation in world society by the formerly colonized populations, exposing them to world culture to a much greater degree than previously. This process works both ways; these newly empowered world citizens began contributing new or refashioned elements to world culture, propagating them through the same channels by which world culture reaches them but with an increasing flow of cultural elements in the reverse direction.

Dimensions of World Culture

Most discussions of world culture focus on its expressive or normative dimensions. Expressive (popular) culture includes media products, consumable goods that often attain iconic status as symbols of modernity or avant-gardism, and foods and clothing styles originating in particular cultures that become worldwide fads. Normative culture comprises the values and desiderata promoted by globally active organizations, be they corporations, foundations, IGOs, or INGOs: fetishistic consumerism and neoliberal economic ideologies, democracy and human rights, religious doctrines and world views, gender and racial equality, environmental stewardship, and so on. The expressive dimension has evoked intense debate regarding the purported homogenizing effects of world culture (discussed below). The normative dimension is most apparent in political struggles regarding the purposes and policies of states, major global governance IGOs such as the World Trade Organization (WTO) and the International Monetary Fund (IMF), and global corporations. Critics of these powerful global actors invoke world-cultural norms and principles in decrying, for example, the refusal of the WTO to consider working conditions in trade agreements, the harm done to the poor by IMF structural adjustment programs, and the damage done to the environment by mining companies. These normative clashes are often widely publicized – challenges to power centers tend to be noticed – so normative claims rooted in the global moral order are the most widely recognized elements of world culture, and they have drawn much scholarly attention as well.

Much less attention has been paid to the ontological and cognitive dimensions of world culture. At the ontological level, world culture is built on assumptions about the fundamental reality of the individual, the disenchantment of nature (the natural world is not inhabited by spirits but operates according to scientifically knowable laws), the usefulness and efficiency of rationalized organization and management, the indispensability of centralized authority structures (states), and so on (Meyer et al., 1987). More specific ontological assumptions stipulate, for example, that individuals are the primary units of action in society, they are educable, they are capable of great accomplishments, and they are subject to many types of physical and psychological maladies that are increasingly well specified. In short, world culture offers definitions of 'the nature of things' – the basic elements of physical and social reality, the technologies available to manipulate these elements, and theories about causal processes operative among them. These theories assure states, corporations, and other organizations that, for example, such major modern institutions as formal education, experimental science, national accounting systems, and advanced-technology engineering are effective means of realizing human goals. Much of this ontological and cognitive material is highly institutionalized and thus largely taken for granted. Science, mathematics, bookkeeping, management techniques, electronic technology, medical knowledge, land surveying methods, principles of roadway design – all these, in world culture – are deemed unassailably useful and effective tools. Their universal applicability is not easily challenged, and they are strongly supported by states, professional societies, consulting companies, and other organizations that deal with rationalized aspects of human life.

Despite their foundational importance for human understanding of the nature of (world) society and the possibilities and prospects of human endeavors, the ontological and cognitive dimensions of world culture are largely ignored by both the scholarly and general publics. These cultural elements are uninteresting, even invisible, for two reasons: one, they operate far below the surface of everyday life; two, they deal

with mundane, routine, matter-of-fact aspects of reality. Ontological assumptions are, by definition, hidden from plain sight; they tell us what kind of world we live in and what is possible in that world, providing the givens of the reality that underlies daily activity. Cognitive elements are, in most cases, produced and elaborated by specialized experts and professionals whose vocabularies and conceptual apparatus are not accessible to nonspecialists. Thus, these highly formalized and rationalized arenas seldom become the focus of ideological debate or controversy, and they therefore are largely absent from the global public realm. Notable exceptions are easily adduced – nuclear power, genetically modified organisms, and global warming have garnered much public attention – but most highly institutionalized forms of cultural globalization stay under the radar.

A third major dimension of world culture is the implicit moral order that underlies such global ideologies as human rights, progress, citizenship, and nationalism. While this dimension cannot be studied directly, it makes good sense to infer that the moral order of world culture embraces the individual as a sacred entity that is to be protected and empowered. The nation is also sacred, in considerable degree, as are national and indigenous cultures, but most collectivities – organizations, corporations, associations, classes, and so on – do not share this exalted status. Virtue is attributed to action, technologies, and structures that enhance or enable sacred entities, while vice is espied whenever these entities suffer injury, degradation, betrayal, or destruction. Variable conceptions of the specific elements of virtue and vice surely flourish in world culture, but a large number of claims about definitions of the good, the just, and the righteous are surprisingly free of controversy or debate throughout world society.

Origins and Expansion of World Culture

Many types of global flows have been rising cyclically for ages, but it was only in recent centuries that a transnational cultural complex took a sufficiently organized form to constitute a recognizable world culture. This crystallizing complex, derived in substantial part from the highly structured transnational culture of the Catholic Church, was primarily European, and from the sixteenth century the imperial Western European countries extended it to most corners of the globe. Europeans promoted political and philosophical principles, societal and individual goals, modes of organizing, and ways of conceiving and manipulating reality that they deemed universally applicable. Epitomized above all by technical and scientific principles and practical knowledge presumed to be invariant across time and space, emerging world culture also included more historically bound constructs and ideologies, such as citizenship, individualism, principles of international law, aesthetic sensibilities, and literary forms. This early version of world culture, perhaps more properly called 'transeuropean' culture, was carried far and wide by missionaries, traders, military expeditions, colonialists, intellectuals, and travelers.

The Western Church played a crucial role in world culture's formative period. The Church was the preeminent transnational organization of the medieval and early modern period. It was the only highly organized structure spanning a large geographical area and a great many local cultures. This structure was the principal means of long-distance communication, spreading all sorts of cultural elements throughout Christian lands. The Church embedded a decidedly transnational culture through the medium of Latin, which was the only widely spoken language, and its personnel circulated among the cities and towns of Europe with surprising facility. Alongside the Church proper, the religious orders that sprang up with such profligacy after the revival of the Church in the twelfth century can be seen as the first wave of INGO formation, in that the orders typically relied on voluntary membership, personal commitment, a transnational outlook, and specialized purposive action to achieve their goals.

In a sense, then, the Church was the original locus of a proto-world culture that, thanks to unparalleled European imperialism, became an important part of truly global culture. The Church provided motivations for some globalizers (missionaries and religious orders) and legitimations for others (traders, conquerors, colonizers) to incorporate the entire world in the nascent world society. It also contributed significantly to the cultural underpinnings of contemporary world culture. The conception of societal progress that prevails almost everywhere stems in part from the Christian legitimation of rational world mastery. The view of the individual as both sacred being and active citizen is rooted in Christian views of the individual, particularly after the Reformation when even Catholics began to stress the importance of individual belief and literacy for salvation. The global script for organizing society in a rational-legal manner derives from the Church's highly successful bureaucracy. More concretely, missionaries not only spread their faith, they also provided education and rudimentary health care in far-flung places, diffusing secular commitments that have since become globally entrenched. Today, distinctly religious views are less obviously influential in world culture yet they still shape its evolution (discussed further below). A vigorous Pentecostal movement, rapidly expanding in Latin America, Asia, and Africa, carries with it the gospel of material success and individual well-being, thus supporting global corporate culture. In counterpoint, the World Council of Churches contributed centrally to global environmental concerns with its initiative on 'Justice, Peace, and the Integrity of Creation,' launched in 1983.

The striking crystallization of world culture in the nineteenth century was evident above all in the rapid proliferation of INGOs, which became the 'structural backbone' of world culture. Increasingly interconnected with each other and with states and business organizations, these carriers of world culture formed an emerging 'global civil society' of voluntaristic, self-governing associations whose members took it upon themselves to organize the world in specific social domains. Typical early examples include the International Charity Association (founded in 1855), the International Sugar Union (1864), the Scandinavian Dental Association (1866), the Permanent International Committee of Architects (1867), and the International Meteorological Organization (1873). By the 1890s, INGOs were appearing at the rate of more than 10 per year across a wide range of social sectors, drawing participants mainly from Europe and the Anglo-American former colonies but also from Latin America and some Asian countries, particularly India. These bodies defined their arena of action as

the world entire, sponsoring conferences, publishing journals and newsletters, and entering into public debate about universalistic issues, problems, methods, and proposed solutions. They became prominent participants in a formalizing global public realm in which world culture was defined, documented, elaborated, and propagated to what the fast-growing number of INGO participants had come to think of as a single world society.

The cataclysmic world wars of the twentieth century severely interrupted world-cultural development but only temporarily. INGOs continued to proliferate between and after the wars, and states became increasingly engaged in transnational cooperative relationships through IGOs. The IGO population eventually burgeoned to comprise hundreds of organizations, while the number of INGOs soared into the many thousands (by the broadest definition, INGOs now number in the tens of thousands). For a good many social sectors, this expanding complex of global organizations came to center on the United Nations, whose agencies and programs emerged as core elements of global governance regimes in such major institutional areas as education, health, environmental protection, and development. INGOs flocked around the UN and many other IGOs to try to influence their programs, policies, and principles, and the confluence of these many forms of organization produced a high degree of formalization regarding many aspects of world-cultural development. This formalization proceeds apace, engaging all states and increasingly large proportions of the world's population.

Homogenization, Heterogeneity, and Conflict in World Culture

Until the late 1990s, globalization was generally seen as a strongly homogenizing cultural force. Globalization was 'Americanization' or 'Westernization', the implantation of the products and cultures of the dominant power centers on the rest of the world. The global popularity of American films, television shows, sports figures, and consumption patterns was undeniable. Western music, soap operas, blue jeans, Coca-Cola, fast foods, and morally lax lifestyles were romping unhindered around the world, and many analysts assumed that the market success of such products necessarily entailed the refashioning of local cultures in line with American or Western tastes and values. Many a worried eyebrow was raised about the spread of an ideology of materialistic consumerism that was obliterating local cultures.

This viewpoint proved too facile (Berger and Huntington, 2002; Appadurai, 1996). Homogenization is certainly evident in some respects: more people in more places are watching television, seeing films, buying brand-name products, and obsessing about one or another pop star. But when anthropologists and sociologists take a close look at the reception of Western cultural products, they find not passive, easily brainwashed consumers but active, engaged receptors who interpret cultural imports in highly varied ways, often with skeptical or dismissive attitudes rooted in local cultures and traditions. Local cultures are not easily abandoned; much creative interpretation and adaptation of cultural imports takes place (Cowen, 2002). Local cultures integrate new cultural elements while retaining their basic identities, in a process known as hybridization (Nederveen Pieterse, 2009). Cultures become more complex and internally contradictory, and hybridization evokes much culture work to make sense of and pacify the contradictions and tensions that result.

One striking implication of this viewpoint, particularly when conjoined with the massive human migration of recent decades, both voluntary and involuntary (refugees fleeing war, famine, and political unrest), is the sharp upswing in cultural and linguistic diversity in the world's cities. In Seattle and Rio de Janeiro, in Amsterdam and Budapest, in Dubai and Mumbai and Bangkok and Sydney, ethnic groups from all continents have become more numerous, more organized, and more active in local commercial and social life. Their restaurants blossom, their community newspapers multiply, their theater troupes become increasingly visible, their languages stand out on store fronts. The net result is a paradoxical form of homogenization: the world's cities are becoming ever more diverse but they are ever more familiar to visitors because they are diversifying in similar ways. This is a telling reflection of world culture in general: it is increasingly complex, diverse, and incoherent, as more cultural elements from a wider range of cultures become globally known, imported, and reinterpreted as they are embedded in local cultures.

The reinterpretation process, often labeled glocalization (Robertson, 1992), implies that even highly standardized elements of global popular culture are subject to varied uses and meanings. For instance, consumers in Hong Kong appreciate McDonald's restaurants as much for their clean facilities as for their food. They expect fast, not smiling, service, and they reserve the right to eat at their leisure. In a city pressed for space, the restaurant has become a gathering spot for youth and a favored locale for birthday parties. In Beijing, McDonald's American origins are attractive to upwardly mobile Chinese as a symbol of participation in global society, but to many Koreans in Seoul those same origins evoke criticism. Popular culture increasingly creates global tastes, but highly variable consumer bases keep this culture from becoming entirely uniform (Watson, 2006).

An anthropological assessment of this situation leads to the conclusion that the world's cultures (national and local, as well as global) are creolizing (Hannerz, 1996) – every locale is an ever greater mélange of cultural elements from many sources. A case in point is West African popular music, an amalgamation of variegated genres (Senegalese folk music, French *chanson*, American blues, British rock, and more) that constitute new and distinctive styles. Retaining indigenous instruments and rhythms, African musicians are not simply on the receiving end; their styles flow back into world culture as well, influencing some of the very traditions from which they borrow. Given the global valorization of difference and authenticity (below), commercial interests intensify this process by promoting diversity widely (UNESCO, 2000). Thus, as new musical and other fads make their way across the globe, they produce new forms of localized diversity and unforeseen local reactions and interpretations. In the expressive realm, the varied forms of local–global interaction are hardly resulting in a standardized, stifling, hegemonic world culture.

Despite this rising diversity, in many other ways world culture is decidedly homogenizing. The complex array of global

organizations that embody, debate, and propagate world culture have produced a wide range of standardized principles, models, and methods for the organization of social life. For example, a basic model of the modern state has crystallized (Meyer et al., 1997). The model is reflected directly in national constitutions, which reveal a remarkable degree of similarity despite some striking variability (regarding, for example, the relationship between religion and the state). It is institutionalized globally through international agreements, such as International Labor Organization conventions regarding labor–management relations, global health programs of the World Health Organization, women's rights declarations, and national accounting principles promoted by the International Accounting Standards Board. The basic model stipulates that the state is responsible not only for internal order and external defense but also for building a modern society and promoting citizen welfare and civic engagement. The state is to organize, regulate, or provide national educational systems, health care programs, retirement and unemployment insurance schemes, and cultural promotion programs, among many other duties. In many sectors, globally legitimated models have emerged to guide states in meeting these responsibilities, such as the standardized educational models developed under UNESCO's aegis in collaboration with educational INGOs and the standardized models for the regulation of stock exchanges promulgated by the International Organization of Securities Commissions.

Although states vary greatly in terms of their historical experiences, resources, and organizational capacity, they have implemented these models in remarkably uniform ways, in a process known as structural isomorphism (Meyer et al., 1997). Isomorphism has been identified in such diverse areas as citizen rights and state authority, school systems and curricula, environmental protection, science policy, children's rights, women's empowerment, same-sex sexual relations, and national planning. Few states successfully implement the models across all these domains, and many states adopt some or many features of the models structurally but make little attempt to actualize them in practice. Nonetheless, the isomorphism process has made states much more similar to one another than one would predict on the basis of the extremely varied capabilities, cultures, and historical experiences of their national societies.

Thanks in large part to the efforts of IGOs and INGOs, standardized global models of organizations have also coalesced in world culture. They can be found across an enormous set of domains: in business, science, medicine, health, technology, recreation and leisure (sports, tourism, entertainment), and much more. Pushed by the carriers of these models (which include business consultants, technical advisers, and academic consultants), corporations, hospitals, research institutes, social movement organizations, and many other types of social units implement the models in largely uniform ways. They also engage themselves in a learning process, constantly monitoring new developments in world culture so they can keep up with the leading edges of world-cultural development. The net result is both a tremendous force for the homogenization of the world and a persistent tendency for organizations in particular social domains to ride the waves of organizational fashion. Businesses are wont to adopt, quite uncritically, 'hot' management techniques, such as Total Quality Management or the Program Evaluation and Review Technique. When such methods go out of fashion, businesses replace them with new 'state-of-the-art' techniques whose usefulness or applicability is more presumed than demonstrated.

In sum, world culture generates both greater diversity and greater homogeneity, in world society as a whole and within national societies. The technical and rationalized forms of homogenization are accepted without much resistance, but expressive and normative homogenization meets with considerable suspicion and, not infrequently, outright hostility. Expressive/normative homogenization is seen as a threat to national and local cultures, and defenders of these cultures are found not only within the threatened societies but also in the rich, powerful (Western) societies that are generally assumed to be the source of the threat. Resistance is often grounded in the principle of cultural relativism (itself of Western origin) and its associated ideology of cultural authenticity. Relativism proclaims the fundamentally equal value of all human cultures. Ethnocentrism is seen as both an intellectual trap and a cause of injustice, while tolerance and, even more, the championing of difference occupy the moral high ground. Outsiders are in no position to judge foreign cultures because they do not understand the internal logics of these cultures or the interconnections among particular cultural elements that make the parts indispensable to the larger wholes. A natural implication of this viewpoint is the claim that, above all, cultures should retain their primordial authenticity. Authentic cultures are to be respected, even revered.

The emphasis on cultural relativism and authenticity undergirds a sense of heightened moral virtue associated with the poor, the excluded, the oppressed, that is, marginal peoples whose right to their own cultures is jeopardized by the onslaught of globalizing world culture. This universalistic form of particularism impels peoples to emphasize or invent traditions and distinctiveness that contrast with the universalistic world-cultural principles that are supposed to operate uniformly in all places. In Western societies, such particularism is stimulated by cosmopolitan connoisseurs seeking authentically exotic cuisine or ethnically distinct 'world' music. In other places, politically astute groups understand the power of reified cultural authenticity as a fulcrum for leveraging rewards from global systems. Hence, distinction and difference have become strategic resources for collective mobilization. In consequence, ethnonationalist movements of many sorts (Basques, Biafrans, Bretons, Croats, Quebecois, Scots, Tamils, etc.) and multiculturalist restructuring by states, churches, schools, and other organizations have become the order of the day.

As this discussion indicates, world culture engenders conflict in world society through a process that has, as it were, turned the West against itself (Leclerc, 2000). By the 1970s, when scores of new states had formed in Africa and Asia, vociferous opposition to continued economic and cultural domination by Western countries (labeled neo-colonialism and cultural imperialism, ideas that also originated in the West) began to penetrate global organizations, especially UN bodies. Various associations of less developed countries called for a restructuring of world society, the fashioning of a New World Economic Order and a New World Information Order that would put restraints on the operations of transnational

corporations and shift resources to the poorer countries. Former colonies began assertively invoking world-cultural principles of equality and development as basic human rights. Further tensions arose as the global human rights sector (itself increasingly involving individuals and groups from outside the West) turned its scrutiny on the new states, decrying their selective championing of certain global universals while ignoring or severely violating others, especially those relating to the integrity and political participation of citizens. Thus, both the particularism of world culture (the moral legitimacy attributed to national or ethnic units) and its universalism (the insistence that all units abide by basic principles and values) yield forms of disagreement and conflict that would not emerge in a less globalized world (Robertson, 1992; Lechner and Boli, 2005).

As non-Western cultures and regions have become more prominent in the world polity, it makes sense to speak of world cultures (in the plural) rather than a singular world culture. Dominant Western models have penetrated deeply in most places, but they have also evoked resistance as well as efforts to revivify and globalize alternative models (Leclerc, 2000). Most notable in this regard is the assertiveness of Islamic cultural carriers, particularly since the 1970s (Roy, 2004). Many Muslim leaders and organizations promote a societal model that infuses the state with religious precepts and recasts the relationship between state and citizen (codified in 1981 as the Universal Islamic Declaration of Human Rights). African and Asian models of social organization and development have also emerged, and some observers argue that conflict in the twenty-first century will revolve primarily around grand civilizational axes rather than the nation-state clashes that have dominated in recent centuries. By the same token, more fine-grained analyses of world culture(s) identify multiple models of central world-cultural constructs. For example, derived from the Western tradition are liberal, socialist, corporate, and welfare models of the state; from Asian sources, quasi-familial and state-led development models. Multiple models of the individual, the business enterprise, and the national polity are further examples. World-cultural complexity has increased rapidly in recent decades, perhaps most sharply since the collapse of Communism and the end of the Cold War, as more cultural centers generate more alternative cultural constructions. Poorer and more peripheral societies are less able to bring their cultural models to the world-cultural table, but many participants in the global arena from richer societies have become strong advocates of the poor and marginalized, helping to ensure that world culture becomes still more complex and incoherent but also more significant for national and local structuration and change.

Globalization, World Culture, and National Identity

Globalization creates ties across space and is therefore often equated with 'deterritorialization'. This feature would seem to spell trouble for nation-states: if globalization transcends national boundaries, states' role in world society should diminish. Focusing on the cultural side of the matter, however, it is clear that the scenario of decline is overstated. As indicated earlier, while globalization challenges nation-states in many ways, the idea of the nation-state is deeply embedded in world culture. World culture provides models of nation-state functioning and norms that legitimate states as constitutive units of world society.

This is no accident: the nineteenth-century wave of globalization occurred during an era of mostly Western nation-building, binding global processes to far more integrated 'national' societies, each with its own claim to cultural distinction. Over time, practice turned into principle, codified by organizations like the United Nations. Newly independent countries mostly adopted the established framework, reinforcing the legitimacy of a single global model for societal organization. The model allowed for considerable variation, for example in the extent to which nation-states comprised actual nations of a single people with a single culture. The striking world-cultural fact is that even highly diverse places witnessed a drive toward greater unity and the development of a distinct national identity, as in the case of Indonesia adopting a new national language.

Homogenization at the national level boosts the institutionalization of global diversity, since each nation's claimed identity differs in principle from those of other nations. A number of global practices endorse and enshrine the value of diversity, from a tourist industry seeking distinctive destinations to UNESCO designating world heritage sites. In this way, globalization 'universalizes particularism'. This is more than a legacy. State institutions continue to reinforce national identities, for example, through formal educational systems that follow a common global script. Important global events, such as the Olympic Games, serve as occasions for the display of distinct identities. Since practices, institutions, and events also press toward commonality, requiring more people in more places to play by the same rules, the reproduction of national identity is yet another instance of the globalizing interplay between homogenization and heterogenization.

Because national identities are so salient and highly legitimated, the glocalization of cultural forms and experiences often involves creative mixing of transnational and domestic elements, as in the case of popular music genres that match national symbolism to global (frequently American-initiated) forms, such as German or Japanese hip-hop. While this may appear to dilute 'authentic' national culture, in some ways globalization also heightens the significance of national identities. Changes associated with globalization – above all, immigration of peoples with very different cultures – are often interpreted as a threat to national identity (Lechner, 2008). Similarly, specifically cultural 'intrusions' associated with globalizing flows may also trigger defensive national responses, for example in the form of quota policies for cultural production or efforts to cleanse a language of English contamination.

Though strongly embedded in world culture, the legitimacy of nations and national identities is contested. New governance structures, such as the EU, have begun to gnaw away at the primacy of national distinctiveness. The sheer scale of global flows makes it ever more difficult to maintain a clear-cut national identity. As more and more individuals sample global cross-currents, they fashion ever more complex hybrid identities. Capitalizing on the growth of the human rights regime, many groups strive to cultivate a form of cosmopolitanism, focused on the well-being of humankind. To the extent

that globalization fosters such trends, it also exposes a continuing tension within world culture.

Religion in Globalized Cultural Context

While much of world culture is decidedly secular, religion plays a special role in it. In fact, all the features of world culture discussed thus far – construction, dimensions, origins, homogenization, and conflict – have roots or parallels in religion. Globalization affords new opportunities for religion and in turn is shaped by it.

'Axial' religions such as Buddhism and Christianity can reasonably be seen as the first world cultures by virtue of their translocal organization, universal message, and highly elaborated concept of 'the world'. As noted earlier, several aspects of contemporary world culture derive from the early history of the Catholic Church and its involvement in the first wave of globalization during European expansion. Religion also figured prominently in the crystallization of world culture in the late-nineteenth century period of intense globalization. Missionary societies were among the most active INGOs, spreading the Christian faith to new places. Other religiously inspired organizations, such as the YMCA, were similarly involved, embracing versions of 'muscular Christianity' that diffused both moral precepts and globalizing sports. Propagating new faiths also became easier, as evidenced by Pentecostalism taking hold in South America (Coleman, 2000) soon after it emerged in Los Angeles at the Azusa Street revival of 1906. Along with such efforts at Christianization, more subtle changes took place as well. As the world drew together in new ways, a new attitude toward religious pluralism emerged. The 1893 World Parliament of Religions in Chicago, for example, brought together representatives of many religions on a relatively equal footing, in an attempt to express the common spiritual concerns of mankind. The World Parliament also signaled that the various faith traditions increasingly were coming to be defined as proper 'religions,' a construct that is itself of Western origin (Beyer, 2006). Speaking of religion as a feature of world culture thus captures a global process in which highly variable 'local' religious experiences gained new significance as part of a more rationalized, standardized world religious domain. To a considerable extent, 'doing' religion is now subject to global norms and standards.

As in world culture more broadly, the Rest challenged the West in several ways after World War II and the decolonization that ensued. Not only countries gained independence, so too did many Protestant churches. In some instances, this occasioned a religious West-against-itself reversal. For example, African Anglicans resisted a more liberal approach to homosexuality in their communion, reflecting wider opposition on the continent to the expansion of human rights in the sexual sphere. As the Catholic Church expanded in the global South, in what some have called 'reglobalization', its membership, leadership, and actual practices further diversified, illustrated partly by the transnational Charismatic Renewal (Csordas, 2009). Overall, the center of gravity in global Christendom has shifted to the South, where worship tends to take a more revivalist form and socioreligious beliefs are generally more conservative (Jenkins, 2011).

Social conservatism also characterizes much of the Islamic world, where resistance to some aspects of modernity has gained prominence in the context of political suppression (Roy, 2004). Globalization, both as actual process and as perceived threat, has had much to do with that renewed religious fervor. Though by no means wholly characteristic of Islam, the resistance takes many forms: Taliban-style attempts at purification, symbolized by the destruction of Buddhist statues in Afghanistan; reform from within, as with Egypt's Muslim Brotherhood after the Arab Spring of 2011; and more violent 'jihad' against mostly Western targets, as perpetrated by globalized militants in loose transnational networks. With few exceptions, however, even such ostensibly oppositional activity still owes much to the world culture it confronts.

As all such examples indicate, religion is of more than historical interest for world culture. If the core of world culture consists of sets of ideas that enable people to act and think as part of one world society, whether in abstract terms or through specific practices, then the current world religions surely count as key components. What 'the world' is about, what human beings are supposed to do in the world, how humans must treat each other as members of a single species, and what lies beyond this world – for millions of people, meaningful answers to such questions derive from religious traditions. Some of those answers fit comfortably with the evolving content of world culture more broadly; witness the Catholic Church's support for human rights or Buddhist endorsement of environmentalism. Other answers fit less comfortably, such as some transnational African religions' conception of the self as inhabited by multiple beings or supporters. Even more challengingly, some world religions question the very categories world culture has inherited from its Western roots, notably the religious/political and transcendence/immanence distinctions, as in forms of Islamic and Asian spirituality, respectively.

World religion stands out as a counterpoint to the notion that globalization entails cultural homogenization. The historic diversity of faiths, reproduced in the modern era, provides the backdrop, but more than reproduction is at issue: globalization facilitates the diffusion of religious ideas and the expansion of religious communities across continents (Wuthnow, 2009), as in the case of Muslim diasporas in Europe and Indian/Hindu diasporas in North America, thus diversifying both those faith communities and the locales where they grow new roots. Nor does diffusion entail simple emulation; a key feature of many transnational religious ventures is the way in which they 'indigenize' or 'glocalize', adapting old models to new places, as in the case of Pentecostal churches absorbing Brazilian, Ghanaian, or Korean symbolism into their worship and teaching. Adding to the diversity of religious expression is the fact that many world religions are very much in flux, strikingly illustrated by the 'spiritual recycling' practiced by Nigerian and Korean Christian leaders reexporting their faith to the West (Micklethwait and Wooldridge, 2009).

Caveats are in order. However great the range of options in the overall religious market created by globalization, local supplies tend to be limited and at times monopolistic. In their daily lives, many religious adherents participate in the same routines as others around the world, guided by common norms. The countries where they reside are subject to the 'isomorphic' tendencies mentioned previously. However

strong their faith, adherents live in a world that operates largely in secular-rational terms set by a world culture that is not evidently grounded in any transcendent faith. Among those who enact and propagate world culture, such as the mostly secular INGOs, specifically religious actors are now in the minority. Yet that same world culture provides space for radically different world views. Deep cultural difference has by no means disappeared; indeed, under new interpretations of human rights, difference has acquired new significance and legitimacy. The differences matter to millions, if not billions. How to manage these differences peaceably, as a source of human enrichment rather than conflict, is a major contemporary challenge.

Overall, religion is a central aspect of cultural globalization: as traditions spread, transnational networks expand, national cultures become more mixed, and new ways of experiencing the world emerge. In many countries, religion mediates the pluralizing effect of world culture. It plays an important role in the intense contests concerning global values and world order. Yet the construction of world culture has become a mainly secular process; it has no transcendent content in the conventional sense. Cultural heterogeneity and conflict themselves take many forms, only some of them religious. While world religion is intimately connected with globalization and involved in the latter's dynamics, it is by no means a dominant force. Whether it can, or should, take on a greater role in defining the desirable world order is likely to be a central issue in future global cultural contestation.

Abstract

This article examines the anthropological interest in globalization from two perspectives. First, in conversation with other social sciences and second, to reexamine classical questions of diffusion, identification, comparison from within the discipline itself. Central to this analysis is the idea of 'flow' that places objects, ideologies, technologies, and images within the dynamic sphere of exchange and circulation. This article also engages with contemporary concerns regarding forceful human dislocation and ensuing violence that are integral to the emerging structures of sovereignty.

The Disciplinary Context

Anthropological interest in globalization is difficult to trace precisely but can be recognized as early as Appadurai's work on the global cultural economy (1990, 1996), Hannerz's analysis of cultural complexity and creolization (1987, 1992), and Friedman's work linking global capitalism and cultural processes (1988, 1994), all of which built on earlier anthropological interest in cultural exchange and world systems. From the start, such work has been part of two sets of scholarly exchanges and debates. The first links anthropology with a wider debate about globalization in other social science fields, notably geography, political science, and sociology. The other is internal to anthropology and links it to longstanding concerns with diffusion, comparison, ethnography, and the study of large-scale historical change. A brief look at each of these contexts might help to frame the anthropological perspective on globalization.

As regards the social sciences in general, anthropologists in the late 1980s found themselves, like many other scholars, trying to understand the processes that led to the breakdown of the Soviet World and to guess at the shape of things to come. They soon found themselves having to engage powerful perspectives on the emergent world order, which came out of the Marxist tradition in geography (exemplified by Harvey, 1989), by a renewed interest in global political culture, exemplified by the polemical and much discussed work of Samuel Huntington (1996), and some prescient studies of the new forms being taken by global capitalism in the last decades of the twentieth century (Lash and Urry, 1987). In addition, anthropologists found themselves in a rich, sometimes competitive dialogue with scholars in literary and cultural studies, notably those influenced by British cultural Marxism, and most powerfully represented by Stuart Hall (1986). In addition, the publication of Benedict Anderson's landmark study of nationalism (1983) provoked a strikingly wide debate about the links between politics, the imagination, and national identification. These stimuli helped to shape anthropological research on globalization, which in many ways is marked by the ongoing effort to link broad structures and processes in the world economy to the subtleties of communication, interpretation, and translation that govern everyday life in all societies.

Within anthropology, the study of globalization is built on several well-established currents of interest. In the United States, the study of globalization fits well with Boasian traditions in the study of diffusion, cultural change, and culture contact and with a longstanding interest in urban settings and complex societies. In Europe, anthropologists were slower to take an interest in globalization; hence, too long-standing interests in problems of scale, social cohesion, and structural change made globalization a subject of growing interest after 1990. In other parts of the world, such as Latin America, Africa, and India, the anthropological interest in globalization was more closely linked to problems of ethics, development, and inequality.

In spite of these various currents of research and theorization within which the anthropological interest in globalization has developed, from the beginning there were serious doubts about whether globalization by its nature was a topic suitable to the special strengths of anthropology in the study of intimate social relations and of societies governed by nonmarket social principles. Many of these anxieties have been translated into methodological concerns, reflected in a significant body of methodological work about how anthropology ought to address the emergent world of globalization (e.g., Fox, 1991). There is still a considerable body of opinion among professional anthropologists that globalization may well be a mere trend, an artifact of academic fashion, and that, in any case, it is not an ideal subject for anthropological research because of its conceptual and social scale. This rearguard anxiety, which is sometimes not easy to distinguish from fear of disciplinary failure, has not prevented a rich set of theoretical debates and empirical studies from emerging out of various anthropological traditions, both in the Atlantic world and beyond. These studies, largely a product of anthropological work since the 1990s, are discussed in the following sections.

Global Cultural Flows

The image of 'flow' has been a central trope of anthropological work on globalization. In the work of Appadurai (1990, 1996), the idea of 'flow' was used to capture a complex dynamic in which objects, ideas, ideologies, technologies, and images were placed in a single economy of circulation, with an eye to distinguish different emergent mosaics of cultural form and social design. In Hannerz's use of this concept (1992, 1996), it was fruitfully linked to Kroeber's idea about large-scale

civilizational and interactional spheres – ecumenes – as well as to ideas about creolization, cosmopolitanization, and the professional networks associated with rapid flows of cultural commodities.

In these early usages of the idea of flow, and in subsequent elaborations of them by others, the idea of flow was sharpened to redress the assumption that cultural flows in the era of globalization were unrestricted in scope and range. A salutary emphasis on boundaries, limitations, selectivities, and exclusions reappeared, thus placing the classic debate between Marxist and cultural approaches once again at the center of attention. This broad interpretive struggle continues (Rockefeller, 2011), and the choices it poses are reflected in many studies associated with the anthropology of globalization, on such subjects as migration (Lomnitz, 2001; Eriksen, 2010; Gingrich and Banks, 2006), colonialism and post-colonialism (Comaroff and Comaroff, 2000a; Mbembe, 2001), media (Feld, 1999; Ginsburg et al., 2002), diaspora (van der Veer, 1995), markets (Hart, 1999; Bestor, 2004), and religion (Csordas, 2009; Rudnyckyj, 2010; van der Veer, 2013).

The positive contribution of the idea of flow was to open up new questions about the relation between legal and illicit flows of commodities and persons, the changing nature of borders and boundaries, the implications of new regimes of financial circulation and cybercommerce, and the evolution of new forms of diasporic identification and mobile tradition building (Nordstrom, 2007; Nordstrom and Carlson, 2014). The image of flows also opens a potential conversation, yet to be fully exploited, between economists and anthropologists on the question of the changes in the world economy suggested by the idea of globalization, and of the best ways of measuring their scale and significance. In a general way, the engagement with cultural flows, their associated economies and interpretations, has marked a decisive shift, in which anthropologists are no longer confined to the study of simple market societies but are addressing such complex phenomena as cybercommerce, intellectual property (Strathern, 2006), and new forms of genetic engineering (Lock and Nguyen, 2010) and marketing. Likewise, the anthropological focus on cross-border flows, as we will see shortly, has opened up a useful conversation between anthropologists, political theorists, and sociologists on new forms of citizenship and sovereignty (Geschiere, 2009; Held and Moore, 2008).

Above all, the focus on flows, regardless of context, commodity, or sphere, has brought anthropology back to one of its earlier insights, namely that most human societies have always been in interactive relations with others, forming spheres of exchange and circulation. Thus, the images of social stability, impermeable boundaries, and natural divisions between ethnic groups, polities, and communities, sometimes implicit in anthropological practice, have been put under sharp scrutiny. In turn, the widespread recognition that societies in the era of globalization are inevitably parts of wider circulatory systems and networks, has posed new challenges for how anthropologists will need to theorize classical models of cohesion, consensus, and order (Appadurai, 2013). At the end of the twentieth century, there was some uncertainty about how to reconcile the undoubted significance of large-scale cultural differences with the reality of the velocity of cross-border flows and the uneven thickness of the membranes between societies, whether organized as nation-states or not. It seems probable that the question of how social order and cultural coherence in lived communities are maintained in the face of complex and uneven cross-border flows will be a major theoretical challenge for the twenty-first century anthropology.

Many of these concerns have produced a special interest in the anthropology of nationalism and a series of contested views about the salience, form, and future of the nation-state as a form of global political organization. The pendulum appears to swing between those (both inside and outside anthropology) who predict the early demise of the nation-state and those who see it as growing stronger than ever. Sometimes, these debates are reflections of actual differences between existing states and sometimes, they are the result of blurring the lines between nations and nationalism on the one hand and states and their powers on the other. The emerging consensus seems to be that while nation-states are unlikely to disappear in the near future, they are evolving their own powers in a transformed ecology of sovereignty. This ecology is affected by changes in the velocity of global capital flows, scale and speed of cross-border shadow economies, and geography of dual, mobile, and diasporic political identifications among citizens. These processes are discussed further below (see Section Sovereignty, Citizenship, and Violence).

The interest in various forms of global cultural flow, and in the nonisomorphic relationship between them, has provoked a strong debate about whether, and the extent to which, globalization is a new social regime. Many voices within anthropology argue vigorously that globalization is no more than a semiotic conspiracy of the media and of global capital and its allies in the world of development. In this view, globalization is only a clever way to repackage colonialism, imperialism, modernization, or various combinations of these ideologies. It is old wine in new bottles. This view runs into the difficulty of having to accommodate too many new animals into an existing theoretical Ark and suffers from the further disability that it does not provide any criteria for recognizing genuine systemic change. It ends history in the name of theory. The more widespread band of opinion among anthropologists is that something surely has changed. The challenge is, as always, to establish what has changed and how it affects the things that have not changed. Thus, there is a renewed interest in how identities are negotiated across multiple locations, how existing structures like witchcraft (Geschiere, 1997) become vehicles and sites for new anxieties and energies, and of how new legal and economic arrangements (those sometimes lumped together under the rubric of neoliberalism) call forth new perceptions of danger, wealth, and risk (Comaroff and Comaroff, 2000b).

Finally, ideas and debates surrounding the idea of global cultural flows have cast fresh light on a classic concern of anthropology, namely the process of identification and the production of identities. These processes have to be reexamined in a world characterized by massive information flow, heightened media images of life possibilities for ordinary people, and new fantasies of wealth and mobility. The rapid growth in mass-market media penetration across national boundaries, the associated growth in the battle between global and national media barons, the projected increase in

various kinds of bandwidth, and the emergent possibility of new, hybrid instruments for cheap, high-speed communication, all combine to change the grounds on which stable cultural identities are produced and secured. Likewise, these factors make it impossible to presume the image of the local as an unchanging ground against which the tableau of global change plays out. Indeed, many anthropologists now have come to take as great an interest in 'the production of locality' (Appadurai, 1996) as in the dynamics of globalization.

With its special interest in language, everyday life, and small-scale social interaction, anthropology is evolving a special purchase on the vast terrain represented by globalization, by paying particular attention to the vagaries of translation and localization and to the special role of language and semiotic mediation in producing new forms of lived experience. This has resulted in a sustained effort to examine the cultural dimension of objects and technologies that have their primary home in the spheres of law, science, and the market. Therefore, anthropologists at the beginning of the twenty-first century studied the organ trade, refugee incarceration, NGOs, musical copyright law, and derivatives, to name just a few examples of social and technical forms whose cultural design is sometimes overlooked. In this proliferation of topics (some of them addressed by other authors in the Encyclopedia), there are some major crosscutting themes, two of which are briefly discussed below.

Heterogeneity or Homogeneity?

Most anthropologists share the widespread presumption that globalization is a new phase in the integration of the world economy, principally powered by new scales and speeds in the circulation of financial capital and the associated explosion in electronic communication technologies. When we recall that the major models of global economic processes have come out of the Marxist tradition, it helps to explain why there is a tendency among some anthropologists to argue that globalization is no more than a new phase in the history of capitalist commodification. From this, follows the possibility that, from a cultural point of view, the forces of commodification will produce increasing levels of cultural homogenization and social standardization, particularly in the realm of media icons, social styles, and consumption values. The further extrapolation, rarely stated explicitly, is that these processes will in turn erase cultural differences both within and across societies. This is the nightmare of globalization as coca-colonization (Hollywood, McDonald's, and Disney are the favored icons of this line of speculation). Yet the evidence is mounting that societies appropriate various forms of commodification in their own terms, media messages are downloaded idiosyncratically, weapons of standardization are frequently subverted to produce further brand differentiation, and the best-laid plans of the standardizers are frequently thwarted by local entrepreneurs and customers.

A splendid example of this process of differentiation is provided in a collection of anthropological essays on the role and style of McDonald's, as it functions in six distinct East Asian settings (Watson, 1997). The ethnographic essays in this collection illustrate that, as a global profit-making organization, McDonald's is certainly eager to create uniformity in its products and in its outlets wherever possible. But the essays also show that in each of these settings, McDonald's encounters a quite different set of needs, anxieties, and possibilities and is drawn into a specific local mosaic of social patterns and cultural orientations, involving age, leisure, work, and freedom. Though McDonald's is a heavily capitalized multinational corporation, with an unerring eye for its local and global profits, its sensitivity to local markets inevitably contributes to the emergence of different desires and practices in its outlets. This does not make it any less a global corporation, but its strategies are regularly bent to fit local wishes and projects. However, these essays also show that this is not a simple matter of Goliath being repackaged to suit David, culturally speaking. In fact, what McDonald's produces in these settings are new and unintended styles and contexts for consumption, sociality, and public interaction, each culturally distinct but not in any obvious or predictable way. Many other studies, especially in the sphere of consumption (involving clothing, music, food, leisure, and housing), also confirm this process.

Heterogenization is not a mechanical product of the sphere of consumption. It is itself produced by local makers of ideas, images, and commodities who give to the culture industries of different societies and nations their own distinctive stamp. Thus, anthropologists have been able to show that the simple distinction that places global producers and uniformity on the one side and local consumers and difference on the other is overdrawn. We have a growing series of studies of cultural production worldwide, especially in the areas of music, film, and advertising, which let us look into the sites and institutions through which global commodities are locally interpreted by producers as well as consumers. The study of 'world music' by ethnomusicologists is perhaps the best developed of these subfields. In general, these studies have produced a broad consensus that cultural differentiation tends to outpace homogenization, even in this most interactive of economic epochs. Naturally, this conclusion fits with the methodological and ethical proclivities of anthropology, with its professional investment in cultural difference and its ethical commitment to cultural diversity. Nevertheless, there appears to be a substantial empirical basis for this consensus. But anthropological interest has by no means focused solely on the good news of cultural differentiation and has not been uncritically celebratory in its treatment of globalization, as the following section will show.

Sovereignty, Citizenship, and Violence

Anthropologists have not failed to notice that the world of global cultural flows is hardly free of suffering, injustice, and dislocation. They have certainly been aware that the incidence and brutality of forced population movements have, in some respects, increased, producing many pockets of human dislocation and frequency of ethnic violence. They have paid attention to the dilemmas of proletarian labor migrants, who struggle with their own translocal loyalties – frequently to religious formations which are themselves increasingly

transnational in scope – against the pressures of the varied ideologies of cultural and legal inclusion that characterize their new homes.

Considered transnationally, poorer migrants face bewildering new combinations of democratic ideology and racist reality. In some cases, such as the oil kingdoms of the Middle East, nonimmigrants monopolize most of the benefits of citizenship. In others, the benefits of citizenship are more widely shared, but everyday racism is a constant threat. In some cases, refugees are drawn into multinational ethnic wars (as in Central Africa in recent years), while in other cases, the revitalization of longstanding ethnonational boundaries flies in the face of intermarriage and ethnic mixing as social realities. In Central Europe, after the death of Tito, the new national constitutions frequently encouraged political campaigns that exacerbated genocidal identities parading as 'primordial.' Many nation-states now practice various forms of cultural fundamentalism and majoritarianism, as they struggle for new forms of legitimation in a global economy. In the process, they increasingly both produce and demonize 'minorities' (Appadurai, 2006). In many of these cases, language, blood, and race are overdetermined icons of peoplehood that force anthropologists to reconcile their own knowledge of the fragility and historicity of these constructions against the popular, lived sense that these realities are timeless, natural, and nonnegotiable.

As anthropologists examine these bloody sites of ethnic violence and violent social purification (Appadurai, 2006; Das, 2006; Feldman, 1991; Malkki, 1995), they find themselves having to study a variety of antecedent and emergent social realities. These include new forms of 'flexible' citizenship (Ong, 1999), new ideologies of citizenship and law (Comaroff and Comaroff, 2000b; Sassen, 1996), new battles over indigenes and outsiders (Meyer and Geschiere, 1999), and new patterns of state-sponsored violence and legality. In engaging with these topics, anthropologists discover that they need to link longstanding professional interests in conflict, bodily ritual, mythologies of origin, and ethnocultural ideology, with new regimes of law, incarceration, borders, and migration.

In particular, anthropologists are now tackling the ways in which the forms of violence and dislocation produced by globalization may be related to new structures of sovereignty, new forms of nationally sponsored globalization, and new niches for the location of the global economy. They thus find themselves in a productive dialogue with scholars in adjacent fields who are making important contributions to these subjects (Castells, 1997; Held and McGrew, 2000; Sassen, 1998). This engagement promises a more sophisticated answer to the question of how new forms of global linkage are also producing new forms of cultural fundamentalism, a question to which somewhat Manichaean answers have been provided in the popular media and its favored public intellectuals in many national contexts. In the United States, and to some extent in Europe, there have been strong alarms raised by economists and development specialists to the effect that globalization is producing both greater wealth and greater inequality. Yet, in popular opinion, especially among the wealthier countries and classes, there seems to be an emergent sense that globalization is a world of the victors in the Cold War and their global allies who have cracked the codes of the global market, the information economy, and the new international order. The losers, in this view, are cultural holdouts at best, cultural terrorists at worst, people who have not understood the new alphabet of the globalized world.

Anthropological work on globalization, in this context, has a challenge and an obligation. The challenge is to take its classical strengths in the study of intimate relations, everyday life, and cultural difference and use them to cast light on circulatory processes that yield local and global results simultaneously. The obligation is to provide a way of thinking about why this era of global integration is yielding at least as much genocidal violence as its democratic voice. That may not seem like a particularly anthropological obligation, but given that anthropology has long tried to create new ways of showing how broad human processes are found in translation, globalization may need anthropology at least as much as vice versa.

Looking Ahead

It is not easy to predict what topics will find special favor among anthropologists interested in globalization in the coming decades. It is likely that some of the broad themes discussed in this article will continue to elicit empirical research and theoretical debate, but it also seems likely that the institutional and geographical range of the anthropological debate will widen. Research institutes, conferences, workshops, publications, and translations concerned with anthropological contributions to the study of globalization are appearing in Brazil, Turkey, Hong Kong, India, and in many other sites outside of the North Atlantic region. In these many sites, anthropologists are building their own critical resources as they engage with specific kinds of national debate, cultural conflict, and research tradition (Appadurai, 1999). Whatever the individual outcomes of this process, two results seem likely. Anthropology is unlikely to remain a bystander in any important national debate about globalization. Moreover, these debates are increasingly unlikely to be determined by scholars, projects, and institutions confined to Europe and the United States. What more appropriate topic could there be for international research than globalization, and what opportunity could be more appropriate for anthropology to contribute to a global scholarly debate about the world we are about to build?

As far as the United States and Western Europe are concerned, anthropologists working from these locations (who are frequently nationals of other countries in Asia, Africa, and the Middle East) are breaking new ground in numerous topical areas connected to globalization. A partial list of some of these important areas would include militarization and counterinsurgency (Kelly et al., 2010), new financial instruments and markets (Appadurai, 2011, 2012; Hart, 2011; Maurer, 2005, 2006; Schüll, 2012; Zaloom, 2006), religion and media (Engelke, 2013; Larkin, 2008; Houtman and Meyer, 2012; Pels, 2012; Spyer, 2009), human–animal relationships (Helmreich, 2009; Ingold, 1994; Raffles,2002, 2010), infrastructure (Anand, 2011; Chalfin, 2010; de Boeck, 2011; Larkin, 2013), ethics and everyday life (Faubion, 2011; Jackson, 2013; Lambek, 2010), the Internet and cyber sociality (Boellstorff, 2008; Coleman, 2012; Ito, 2009; Miller and Slater, 2000; Turkle, 2011). These

emerging interests deepen the conversation between anthropologists of globalization and scholars in other disciplines. They reflect the classical interest of anthropology in the question of what it means to be human, and ask also what this question means in an era in which the human, the global, and the planetary have become overlapping forces in our worlds.

Globalization: Geographical Aspects

This article is a revision of the previous edition article by A. Amin, volume 9, pp. 6271–6277, © 2001, Elsevier Ltd.

Abstract

This article examines the nature of geographical thinking about globalization and contrasts the nature of geographer's theoretical contributions with other social science disciplines. It argues that geographical thought on globalization provides a distinctive set of insights into the spatialities of globalization which can be of great utility to the central concerns of a range of social science disciplines, and which address some of the limitations identified in the wider globalization debate. It aims to illustrate these geographical ideas through consideration of the geographer's work on global economic developments and city regions.

Introduction

Globalization continues to be one of the most widely used concepts by social scientists to describe and explain how contemporary world society is changing in the twenty-first century. Yet much of the globalization debate of the last 30 years has only intermittently and often partially engaged with the complex spatialities of globalization processes and global societal integration. During the 1990s, debates about globalization were often framed around simplistic understandings of globalization as creating homogeneity and sameness (Bisley, 2007) and the long-standing simplistic idea that this constitutes an 'end of geography' (cf O'Brien, 1991; Friedman, 2007). While the last decade has seen a more diverse and sophisticated approach to understanding what globalization 'is' (as a complex set of tendencies rather than a singular process or end state (Dicken, 2011)), much discussion of globalization within a range of social science disciplines still does not foreground the intrinsic spatiotemporal nature of the transformations it is associated with (Jones, 2010). In this article, I want to argue that this is a significant ongoing limitation in the effectiveness of globalization theories, and that a wider integration of geographical theorization of globalization provides scope to address this. In that respect, it seeks to demonstrate how geographical thought – not always utilized by globalization theorists more widely – provides a range of epistemological insights and theoretical concepts that can both inform and enhance social scientific theories of globalization in a way that permits a more sophisticated understanding of the complex set of phenomena captured by the term. It is, therefore, an (albeit) modest manifesto for a much wider integration of geographical approaches to understanding globalization than has hitherto emerged across the social sciences.

Geographical Thought and Globalization

Geographical thinking has been criticized – certainly within the discipline – for standing on the margins of the so-called mainstream globalization debate that emerged during the 1990s (Dicken, 2011). With a few notable exceptions such as Doreen Massey, David Harvey, or Peter Dicken, geographical thinkers did not figure in the wide-ranging meta-theoretical accounts of globalization that emerged from a range of social science disciplines (and in popular commentaries) (cf Harvey, 1989, 2003, 2006; Massey, 1994, 1999; Dicken, 2011). It was political scientists, sociologists, and urban theorists who put forward all-encompassing theoretical accounts of the development of globalization as a phenomenon – obvious examples being the contribution by David Held and his co-authors, Jan Art Sholte, Manuel Castells, George Ritzer, or Saskia Sassen (cf Held et al., 1999; Sassen, 2001, 2007; Castells, 2009; Ritzer, 2009). From one perspective, geographical thought has missed an enormous opportunity (Dicken, 2011) in making both a distinctive and sophisticated contribution to understanding this complex and contested phenomenon.

Yet another reason for the lack of prevalence of geographical thinking in the so-called mainstream globalization debate is that geographical thinking quickly adopted a critical and skeptical perspective on social scientific meta-theories of globalization (Jones, 2010). This was not the skeptical 'school of thought' identified by Held et al. (1999) as doubting the pervasiveness of globalization both as state of society (defined as global societal integration as the planetary scale) and of globalization processes (e.g., Hirst and Thompson, 1999), but rather a skepticism at the utility of the concept and the coherence of a meta-theoretical approach that placed globalization at the center of explanations for a multitude of societal phenomenon (Jones, 2010). For geographical thinkers, the globalization debate that continued into the new century after a wave of debate in the 1990s often appeared simplistic and naive, deploying an unsophisticated spatial epistemology that failed to capture the nuances, diversity, and sheer complexity of contemporary global societal integration (Cox, 1998; Taylor, 1999; Sheppard, 2002; Amin, 2002). Geographers have long made use of a plethora of spatial concepts – space, place, proximity, territoriality, boundaries – that did not fit easily into the dynamics of a globalization debate that raged around polarized caricatures of integration (Amin, 2002). The proposition that globalization corresponded to 'the end of geography' (O'Brien, 1991), creating a 'borderless world' (Ohmae, 1995; Fung et al., 2007) or producing truly global corporations (cf Jones, 2005) – counterposed against historical analyses that nation-states remained the key building block of the international system and that trade was not more radically 'globalized' than the interwar period – did

not provide much theoretical traction in the context of geographical debates about uneven development (Cox, 1998; Brenner, 1999; Smith, 2008), the construction of global production networks (GPNs) (Yeung, 1998; Henderson et al., 2002; Coe et al., 2004), or the fractured nature of urban political movements in different world cities (Amin and Thrift, 2002; Brenner and Keil, 2006). From these vantage points, critical interventions within these debates were at times of limited value since it amounted metaphorically to shooting a series of conceptual and epistemological ghosts. None of the positions characterized by Held et al. (1999) – globalist, skeptic, or transformationalist – served to fully capture the way in which geographical thinking was engaging with the concept of globalization (Jones, 2010).

In this respect, geographers have developed what can be seen as a more multilayered and complex view of the spatiality of the phenomenon associated with globalization which has not been willing to treat globalization in the singular, and which accentuates the variable and uneven spatial configurations of social relations in the period of contemporary globalization. Such an approach contrasts with other disciplines insofar as it can be argued that geographical thinking about globalization has taken a broader and more holistic approach that has been less disposed to focus on a particular dimension or epistemological 'cut' on the concept. For example, in economics and business studies, for example, earlier studies of globalization focused on the implications of the emergence of a supposedly borderless economy (Ohmae, 1995) (driven by international market integration, global flows of money and information, and transnational production and regulation) on national and subnational economic sovereignty, competitiveness, and growth. By the 2000s, these disciplinary approaches were widely characterized by a proglobalization or 'globalist' (Friedman, 2000; Wolf, 2004) perspective that focused on the economic characteristics of globalization, and was grounded in a view of the benefits of liberal international markets and an increasingly cosmopolitan and democratic global society (Friedman, 2000; Wolf, 2004). The optimists celebrate the offer of new market opportunities, and the capacity of economic and social interconnectedness to deliver greater material well-being for a growing proportion of the world's population including those in less developed countries (Bhagwati, 2004).

In contrast, within political economy and international politics, the discipline has been characterized often by a more critical and skeptical understanding of globalization based on the disciplinary concern for the nation-state, national borders, and the nature of global governance and political structures (Berger, 2000; Swank, 2002). During the 1990s, historical-based analyses doubted that contemporary globalization was as unprecedented or novel as the globalists claimed (Hirst and Thompson, 1999), while more recent political economic contributions have focused on the discursive dangers of neoliberalism, the problems created by a global economy dominated by a small number of powerful transnational corporations (TNCs), and the growth of wealth inequality across the planet (Strange, 1997). In politics and international relations, thinkers have also been concerned with a wide-ranging debate centered on the erosion/reformulation of the nation-state as a unit of authority (e.g., Holton, 2001; McGrew and Lewis, 2013), following the rise of non-state institutions of regulation and governance (e.g., Garrett, 2000), and on the challenge to citizenship and democracy posed by the rise of transnational political organizations (e.g., global NGOs) as well as plural, non-national sources of political rights and identification (e.g., EU citizenship) (e.g., Jacob and Neumann, 2006). More recent work has grounded such interventions around increasingly vexed challenges in confronting the governance of global climate changes, conflict management, or the postcrisis global financial system (Palan et al., 2013).

Of course this argument should not be taken too far. Clearly there has been and there remains considerable overlap in the way geographers have engaged with globalization processes with other disciplines, and questions of the complex spatiality of globalization have also been substantially engaged within those fields. This is certainly the case in sociology where extensive consideration of the spatial constitution of globalization underpins much thinking (e.g., Giddens, 1990). However, much of the debates have still been dominated by contributions that seek to develop broad conceptual frameworks – or overarching meta-theoretical accounts – of globalization that span a diverse range of societal transformations. Within sociology and cultural anthropology or cultural studies, there has been wide-ranging engagement with globalization through the lens of the global informational society (Castells, 2009), the nature of cultural globalization (Appadurai, 1996; Tomlinson, 1999), or attempt to develop an overarching sociology of globalization (Sassen, 2007). Much attention has also fallen on the implications of information and media technologies (Castells, 2009), global consumerism (Hopper, 2006), and international mobility (Shamir, 2005) which is generating a mixing of identities and lifestyles in different local settings. Through these contributions, there is certainly overlap with the spatial concerns of geographers but the concern for spatial difference is secondary to the role of a global-scale meta-process or phenomenon. A good example would be George Ritzer's theories about the erosion of local difference under the weight of the same world products and consumption norms and the same global corporations (i.e., the so-called MacDonaldization of society) (cf Ritzer, 2011). A sensitivity to the persistence of local difference is engaged within this work, but there is less focus than a geographical perspective would adopt on the nuances of local change resulting from heightened global exposure and virtual and real linkage with different parts of the world.

In foregrounding the diverse nature of globalization's spatial implications, geographers have therefore taken a distinctive epistemological approach to globalization when contrasted to other social science disciplines. But this has also occurred in a context where over the last decade, the wider social scientific debate has become ever more fractured and diverse in its analysis of globalization (Jones, 2010). Bisley (2007) argues that debate can be characterized by at least five cross-disciplinary phases and in that sense it is becoming more difficult to characterize a particular disciplinary 'cut' at globalization. Political thinkers adopt both globalist and skeptical views of the phenomenon, while cultural thinking is becoming ever more influential on those concerned with the global economy or the nature of transnational firms or markets (e.g., Edwards and Rees, 2006; Gertsen et al., 2012). At the same

time, many of the subdebates within social science disciplines have become more nuanced in both their engagement with the specificities of globalization processes and also in their conceptualization of the complex spatialities manifest in contemporary global transformations. Management theorists have engaged with the complex spatial form of firms as transnational organizations (Dunning and Lundan, 2008), and political economists increasingly viewed debates on the interactions between state and suprastates as requiring a spatial epistemology that moves beyond states as territorial containers of institutions and political systems (e.g., Boyer and Drache, 1996). A consequence of this is that interest in some social science disciplines in the existing work of geographical thinkers on globalization has increased, and it has also opened up the interdisciplinary scope for a more sophisticated theoretical framing of the array of phenomena captured in the concept of globalization. In order to further argue for the distinctive potential of further engagement with geographical thinking in this respect, the next task is to provide further insight into how geographer's conceptualization of globalization has evolved in the last couple of decades.

A Distinctively Geographical Approach to Globalization?

During the 1990s, geographers developed a theoretically diverse and skeptical view of many of the globalization theories – and especially the meta-theoretical frameworks – in other social science disciplines. This stemmed from both a diversity of approach within the discipline, and also a spatial onto-epistemological perspective that intrinsically questioned the foundations of all-encompassing theories of globalization. Thus, while there are parallels to the sociological theorization of Giddens which that argued that globalization was at root a radical reconfiguration of social relations in space and time in the contemporary period (and developed by Held et al., 1999 in their (revised) transformationalist approach (cf Jones, 2010)), geographical thinking tended to deploy a more nuanced and complex understanding of spatiality that made use of a variety of concepts not widely developed in the rest of the debate. Such concepts as scale, place, distance, proximity, territoriality, and different forms of 'space' occupy the geographical literature. Geographical thinking was thus instinctively dissatisfied with the meta-theoretical deployment of concepts such as 'deterritorialization' (Elden, 2005), as manifesting one generalizable phenomenon applicable to every globalized social relationship – an underlying basis for some of the broad theories of globalization developed in other disciplines.

This appreciation of the complexity of the social spatial in the era of contemporary globalization thus in part accounts for the lack of an ambitious geographical meta-theory of globalization, but also important is the internal debate and diversity of theoretical perspective within the discipline when it comes to conceptualizing globalization. A key debate in this respect was that around the concept of spatial scale, with the broader globalization debate's sometimes binary usage (and conflation) of the global versus local scales serving to emphasize the need for a better theorization of different scales. A key contribution was that of Marston (2000) who reviewed the then state of the debate in political geographical thinking to conclude that within geographical theories, spatial scales (local, regional, national, global, supraregional) have no pre-given or fixed ontological status, but are produced and reproduced and continually transformed socially by the imperatives of social relations in world society and economy (cf Swyngedouw, 2004). In that sense, territories and scales were understood as being continually (re)produced (cf Agnew, 1999) and thus historically constituted (see also Agnew, 1994; Cox, 1998; Taylor, 2005; Smith, 2008). Neil Brenner, for example, argued that "the post-1970s wave of globalization has significantly decentred the role of the national scale as a self-enclosed container of socio-economic relations," and we are "witnessing a 're-scaling of territoriality'" which includes the increased "importance of both sub- and supranational forms of territorial organization" (Brenner, 1999: 435). In this geographical understanding of globalization, the phenomenon can be seen as the multiplication of geographical scales of social organization, linked to the changing spatial requirements of the latest phase of (capitalist) societal development. These are not seen as parallel or mutually exclusive scalar geographies, but intersecting and overlapping ones, with places/territories implicated in the full variety of scalar reorientations. Thus, this provides significant theoretical tractions to the contention that we are not witnessing an end to geography in a globalizing totality but rather a rescaling of boundaries (upward, outward, and downward) and a reconfiguration of territories as they engage in multiscalar processes and politics (Amin, 2002).

Importantly, all these geographical thinkers argued during the 1990s that contemporary globalization was associated with the rise of new territorial scales of organization, and new territorial boundaries, rather than the replacement of old, national scales and boundaries by a unitary global field of meaning and action. Contra to Manuel Castells, they did not see the replacement of an old world as 'space of places' with a new 'space of flows' – at least in any simplistic sense. Nor did geographical thinking sit comfortably with the idea that globalization could be easily reduced to one process or phenomenon (in line with Anthony Giddens, Jan Arte Scholte, or David Held and his co-authors), at least beyond the very broadest level of generalization. Rather, geographical approaches argued that to fully understand globalization, there was a need to recognize and engage with the persistence of geographical unevenness and diversity.

However, in the last 15 years, this debate around globalization in geography has not remained static, and the concept of scale in this context has become heavily contested and debated (cf Berg, 2004; Marston et al., 2005). This was because a range of contributions argued that scalar concepts did not permit a sufficient understanding of how places, spaces, and territories were themselves being transformed through global societal integration (Thrift, 1999; Murdoch, 2006). Amin (2002) argues that the scalar approach provided "little concession" to the "possibility that traditional demarcations between spatial and territorial forms of organizations might be blurring" – a consequence of globalization processes. Amin's well-cited argument is that theories of globalization need to account for the ontological presence of the proximate and the

remote at the same time in a globalized world. Geographical theories have thus moved to recognize that places such as cities and nations continue to exist as territorial units, but now with different external orientations (e.g., as sites in GPNs or places dependent upon international investment or competitiveness) (Coe et al., 2008; Massey, 2007; Dicken, 2011) and different scalar involvement (e.g., national welfare policies, continental trade agreements, global environmental regulations, local tax regimes) (Bulkeley, 2012; Bulkeley and Schroeder, 2012; Bridge and Le Billon, 2012). The boundary between place and space is not seen to be bending or disappearing – a line in shifting sand – but as a remaining line of distinction between 'in-here' relations and institutions, and those 'out-there' (cf Amin, 2002; Massey, 2005). Global connectivity is seen in that sense as leading to the 'nesting' of territories into multiple scales, rather than territorial places becoming uncoupled from a geography of scales within which they 'nest' (Lagendijk, 2002).

In the next section, we move to consider how this more recent work has opened up a new set of theoretical approaches to globalization which further problematized the dualist distinction between the 'local' and the 'global' in much globalization theory, and has moved to a 'postscalar' approach which increasingly regards the reconfiguration of the spatiality of social relations as a central aspect of contemporary globalization.

The Need for a Relational Approach to Space and Place

In the early 1990s, Doreen Massey (1994) coined the oxymoronic phrase 'a global sense of place' to deliberately seek to conceptualize localities in 'nonscalar' or 'relational' terms, arguing that places in today's globalized world increasingly should be understood as sites of juxtaposed social realities, shaped by the layered historical connections and geographical links that are to be found within and beyond them (Massey, 1994). Their character as sites of or physical contexts for agglomerated activity has thus far less to do with the properties of a territorial system (e.g., localized linkage, self-regeneration, local governance) than with the effects of spatial and temporal exposure and connectivity (e.g., continual and open-ended change, juxtaposition of differences, overlapping of networks of different global connections). Two of Massey's now famous examples of places as 'open, porous, hybrid' (Massey, 1999: 21) are Mexico City, with its varied architectures revealing layers of global Spanish and American-Indian historical connections, and Kilburn High Road in London, with its juxtaposition of English, Irish, and Indian diaspora lifestyles and connections. In her more recent book on London, Massey (2007) develops this argument about the way in which world cities are relational places, whose political, economic, and sociocultural nature can only be understood through an analysis of the intersection of local and distant relationships. Her account seeks to unravel how social inequality, industrial restructuring, and political identity are all caught up in a variety of global-scale interconnections of differing strengths and influences at different points in the last 50 years.

It is this approach that marks Massey's distinctly geographical approach to the spatiality of what are often loosely referred to as 'globalization processes,' and how they are manifest in place. For Massey, the spatial in general is "a sphere of the juxtaposition, or co-existence, of distinct narratives, as the product of power-filled social relations" (Massey, 1999: 21). In this respect, although exemplified well in a leading world city, a global sense of place is needed not only for cosmopolitan places such as London, but for *all places*. Every place may be imagined as 'particular articulations of these social relations' which includes 'local relations 'within' the place' and also 'those many connections which stretch beyond it' (Massey, 1999: 22). The important consequence of this insight is that places are open, porous, and hybrid – their uniqueness comes not from some mythological essence of rootedness or an isolated history, but from the absolute distinctiveness of all the mixtures of near and far influences that are captured by and through them over time (cf Massey, 2005).

Such a conceptualization of the spatiality of places stands in stark contrast to the rather simplistic homogenization view of globalization making all places the same – a perspective that had gained some traction in its most simplistic form across in popular debates about globalization. On the contrary, what globalization becomes in this framework is the contemporary and ongoing restructuring of space/time through places. For Massey, globalization is thus a "remaking of those, inherited but always temporary and provisional, spaces, places, cultures which are themselves the hybrid products of previous restructurings" (Massey, 2005). But of course places are themselves composites of multiple social relations – individual, collective, organizational, and institutional – that are differentially constituted through proximity and distance (Jones, 2009). This is where geographical thinking reaches the limits of the utility of understanding anything as existing at one scale; the nub of this issue is that it is arguable that any given set of social relations notionally 'within' a locality can in fact be understood to exist discreetly at one scale or the another. Local encounters are no more 'essential' than nonlocal practices and customs (Swyngedouw, 1997; Amin, 2002) (even if a purely local or nonlocal practice could be identified which is itself problematic (cf Jones, 2010)). Recent geographical thinking about economic practices, for example, has begun to seek the translocal extension of certain practices which are constituted simultaneously in their enactment by proximate co-present social relationships and those mediated at a distance (often by information or communications technologies) (Beaverstock et al., 2010; Hall et al., 2009; Faulconbridge and Muzio, 2009). The development of transnational firms and their associated global economic productive spaces is one fertile example of how these ideas have been developed, and recent work on the nature of cities and regions in today's global world is another. We will now consider each of these in turn to understand these arguments in more depth.

Globalized Corporate Spaces

Geographical thought on the nature of the global economy has made increasing use of a relational approach (Yeung, 2005; Bathelt, 2006; Jones, 2014) that has focused on the nature of the relationships between actors in the global economy. This

relational approach has been both at the level of firms and between key individuals within firms and other economic organizations in order to understand the complex spatiality of global economic transformations. In theorizing economic globalization as producing a range of global economic spaces (territorial, social, organizational, technological) (cf Jones, 2009), economic geographers have developed a range of conceptual cuts at demarcating sets of social relations that provide insight into the complex spatialities of global transformation. I want to briefly identify two of the most significant fields of work that have been developing this postscalar relational approach.

The first is the body of work that surrounds the concept of the GPN. Originating in the empirical of the so-called Manchester school on transnational firms and the geography of global production activities (Dicken et al., 2001), the development of these ideas predates the emergence of the mainstream globalization debate in the 1990s. Peter Dicken's work in the 1970s and 1980s began to outline the theoretical implications of an empirically identifiable 'global shift' in the location of manufacturing industries to the (then) newly industrializing economies of Asia (Dicken, 1986). By the 1990s Dicken argued that this shift constituted a radical geographical organization in production in the global economy, and developed with colleagues the concept of the GPN to conceptualize how transnational firms were locating different aspects of production process across a planetary scale and through complex relationship with subsidiaries and supplier firms (cf Coe et al., 2004). Important in these analyses has always been a reconceptualization of the spatial existence of firms as economic actors in an era of global economic integration. The GPN literature that developed during the 1990s posed an important counterbalance to the narrower epistemological framings of firm-level globalization that were being utilized in international business or management studies – notably, accounts of the emergence of multinational enterprises and their development into more transnational forms while remaining strongly wedded to their home economy territories (e.g., Rugman, 1996, 2001). GPN work within economic geography argued on the basis of detailed empirical studies of firms and sectors that TNCs were increasingly organizing production through highly complex and uneven planet-level networks through branch plants, subsidiaries, outsourced supplier networks, and just-in-time production techniques (Coe, 2012). Importantly, this work also demonstrated how corporate success in the global economy for these TNCs was increasingly tied into complex webs of relationships both embedded in but also transcending local and global-level contexts (Hess, 2004). In this respect, this important field of economic geography has reconfigured understanding of the spatial existence of firms and the complex relationship between territorial production sites and distant actors.

A second strand of economic geography has, however, also developed a relational approach using the role of key individual firm managers and economic practices as a contrasting means to better understand the organization and development of global economic activity. In particular, a body of work has used such concepts to theorize the development of a range of 'postindustrial' sectors that are becoming increasingly important in both developed and developing economies (for example, finance, advanced business services, cultural and creative industries). At both the theoretical and empirical levels, geographical work has sought to understand the key role of globally connected and mobile senior managers in shaping the way in which firms globalize production, enter new markets, and engage in innovation. Geographers have thus engaged with the nature of 'corporate globality' (Jones, 2003; Beaverstock, 2004; Strom and Mattsson, 2006; Hermelin and Rusten, 2007) with respect to understanding how transnational firms generate coherence in strategic, operational, and coherence terms. Geographical work has also shed new insight into how specific industries have globalized in different ways, shaped by the specific nature of the work processes (Gertler, 2003) and mobilities (Beaverstock et al., 2010), geographies of their markets (Zook, 2001; Gluckler, 2006), access to financial networks (Wray, 2012), or the need for certain types of labor (Cumbers et al., 2008). Examples include the uneven nature of internationalization in legal service firms, the transnational financing of large infrastructure projects (O'Neill, 2009), the very specific way in which the global architectural industry has emerged (McNeill, 2008), or 'global managers' who can manage complex global organizations in multiple intercultural contexts (Schlunze et al., 2012).

Cities and Regions in a Global World

Another strand of urban and regional geographical work has made significant contributions around how we might theorize contemporary economic agglomeration and the spatiality of global economic actors within regions, also increasingly drawing on nonscalar and relational approaches. Both economists and economic geographers have developed a body of work that seeks to better understand the clustering of economic activity in cities and regions as the outcome of powers of proximity, arguing that in an era of greater globalization locally embedded aspects of economic competitiveness have become ever more important. Much focus has thus been on the way that physical or territorial proximity leads to economic success by encouraging trust, reducing transaction and communication costs, and creating knowledge spill-over and/or creative buzz (cf Storper and Venables, 2004; Glaeser, 2011) and accounts which continue to see an economic place for regions or cities contrast the global as a scale of distanciated links, fast flows, and world-scale processes, with cities' regions as the sites of face-to-face-contact, or centers of agglomeration among global networks (e.g., clusters of transnational head offices) (Pain, 2008).

Yet a relational conception of these places provides a more sophisticated understanding of the nature of these territorial agglomerations of economic activity and reveals the complex nature of proximity and distance captured through these physical territorial spaces. Geographical work contrasts with the spatial epistemology of economists by seeing cities and regional economic clusters (for example, regions such as Silicon Valley) as contexts in which diverse geographies of linkage coalesce rather than just being concentrations of activity in territorial spaces (cf Ibert, 2010; Storper, 2013). Contemporary information and communications technologies, combined with global transportation infrastructure, mean that economic activity in a cluster of firms or an urban business

district is a continual mélange of near and distant relationships, played out across an uneven multiscalar set of dynamic relationships. For example, a software firm working with Facebook or Google in Palo Alto (in Silicon Valley) is reliant on a range offace-to-face interactions in its daily activities between co-present employees mixed with ICT-mediated interactions with others in firms elsewhere in the region, the United States, and planet-wide. The same applies to a media firm in London, small ICT firms in west Africa, or the research and development activities of engineering firms in northern Scandinavia (Grabher, 2006; Murphy, 2013; Ahlqvist, 2013). What matters is the interplay of a web of multiple relationships that produce proximity in a range of way that exceeds the physical around technological, social, cultural, and organizational dimensions (Jones, 2009). Global business spaces exist in this manner, always articulating in part in and through places, but not reducible to the attributes or confines of those places.

In this way, a relational understanding of global economic space recognizes places as clusters of overlapping network sites, without seeing in them only local economies of association restricted in their scope to a territorially localized economic system. It views with skepticism territorial metaphors such as 'local fixity vs global flow,' 'embedding the global,' or 'the local in the global' which often unhelpfully 'defend' the space of local economy against global 'encroachment.' It also dispels the binary division of these spatial categories. Instead, it highlights that local economic activity which is part of, and inseparable from, proximate and distanciated transactions, and that whatever counts as the local has to be seen as a networked space that exists dynamically in and through territorial spaces, not as a purely territorial phenomenon itself. Such work therefore seeks to develop a theoretical approach to understanding how place-specific and 'translocal' relationships are simultaneously and continuously caught up in the way veconomic activity becomes embedded in certain regions (Hess, 2004; Jones, 2008).

Conclusion

This article has aimed to provide an overview of how geographical thinking has offered a range of epistemiological and theoretical insights into the nature of contemporary globalization, and how social scientists in other disciplines might make use of its approach in developing more sophisticated approaches to the spatiality of globalized phenomenon. Geographical thinking has in many respects opened up a series of challenges for social scientific thinking to consider critically how many of the actors and entities that are the subject of social scientific enquiry – whether they are nations, cities, territories, corporations, organizations, or even individuals – exist as spatial phenomenon in today's increasingly integrated global society and economy. Relational and nonscalar thinking within geography reconfigures the terms of the social scientific debate about the impact globalization on places, as well as how we understand the nature of the spaces in which social phenomena exist and in which social practices are undertaken. This presents a potentially powerful toolkit for a range of objects of study that concern social scientists whether they are economic, political, or cultural phenomenon in today's globalized world.

The latter part of this article illustrated this approach through discussion of two strands of geographical thinking around global economic actors and the nature of city and regional economies, but within current human geographical work on globalization there are many more possible examples of how nonscalar and relational approaches (loosely defined) to space and place are being deployed. Other important areas of geographical work are concerned with the nature of urban politics and cultural/political practices are undertaken through different spatial configurations and are fluid in space and place (Amin and Thrift, 2002; Amin, 2012; Brenner, 2014). Equally political geographical work has sought to understand the multilayered spatialities of governance that perforate boundaries of territorial scalar units, as well as the role of nongovernmental actors in the politics of place in the contemporary global society (Taylor, 2005; Sparke, 2005). In that sense, the aim of this article has been to provide a partial insight into how geographers have addressed the concept of globalization, rather than a comprehensive overview of the breadth of this work. There is a great deal of human geography that could have been drawn upon to illustrate further examples, since with the discipline's central concern for understanding the nature of spatiality globalization is often at the center of contemporary geographical concern. Central to this is the capacity of geographical thinking to pose a challenge to a substantial proportion of ongoing work on globalization that still tends to construct globalization processes as unifying and homogenizing transformations (albeit in a more nuanced way than in the 1990s), rather than putting the diverse and uneven nature of global interconnectedness at the center of social scientific analysis. In that respect, geographers continue to have a significant and important offering to those who would better understand the nature of globalization across a wide range of social science disciplines.

Globalization in Education

Abstract

Globalization has brought about tremendous changes to every aspect of human life in the twenty-first century. Education, traditionally a local practice confined by geographical and political boundaries, has too been affected. This article reviews the emerging trends of globalization in education. Specifically, the article discusses the trends of global standardization of education, global enterprising of educational systems and institutions, global migration of students, and the need for global citizenship. The article concludes with discussions of the most challenging issues facing education in the age of globalization.

Humans have entered the age of globalization. Thanks to advances in communication and transportation technologies, the physical distance that used to separate human societies has been disappearing in recent decades. For some practical purposes, physical distance is dead, in that it no longer matters in terms of time and costs. As a result, the primary living space, that is, the space a human individual or society can act in and impact, has become global, no longer constrained by the physical location of their presence at the time (Zhao, 2009a). Information, people, and goods move as freely, fast, and frequently from one place to another on earth, as they used to in much smaller spaces such as a village or geographical region (Legrain, 2002; Giddens, 1991; Friedman, 2007; Stiglitz, 2006).

While there are different definitions of globalization, which as a concept has only begun to be written about explicitly over the past three decades, the gist is the process and result of worldwide economic, social, cultural, and political networks that could only exist in much smaller geographical spaces before. Globalization may not be new, according to some (Friedman, 2007). It has happened before but the scale of participation, the pace, the intensity, and frequency were much less in the 1600s than what we witness today. The nineteenth century steamboats undoubtedly shrunk the distance between Asia and Europe, but the efforts, time, and costs it took to get to Asia then were still prohibitive to most individuals, in comparison to today's jet airplanes. The cultural and political ignorance then practically prohibited most people from equal participation in global commerce.

Today, despite the different views about the consequences of globalization (Friedman, 2007; Stiglitz, 2006), it is theoretically possible and economically real that the majority of the people on earth are participants of the globalized world. We wear shirts that are made by people in many different countries. Hundreds of millions watch the same sports event simultaneously from all parts of the world thousands of miles away. McDonald's, the American fast food giant born in Chicago, has stores in over 120 countries. Suhas Gopinath, an Indian boy from a poor family, developed a multimillion-dollar company creating Web sites for American businesses when he was 14 years old (Salkowitz, 2010). In 2013, over 230 million people lived in a country different from where they were born, compared to about 150 million merely 20 years before (Connor et al., 2013).

The potential for anyone to engage in activities on a global scale without considering geographical distance has enabled multinational corporations to spread their production all over the world, market products to people in the remotest areas of Africa, and employ people from any part of the globe. It has also made it possible for any individual to take advantage of the same mechanism to join the global production chain, to market their talents to people in faraway places, and to consume goods produced in remote places. The implications of this potential are not fully understood and may never be as globalization continues to evolve and will always be a dynamic process. However, it is obvious that from now on, all human activities must be considered in the context of globalization as they will always be affected by forces of globalization.

Education is a universal human activity. Although traditionally conducted mostly in local contexts, it has been affected by globalization in recent years. But because of its historical nature of being an extremely local activity, governed by local economy, culture, and politics, education has been slow in response to globalization in comparison to economic activities. Judging from recent activities, this is likely to change. Globalization in education is speeding up and will probably become one of the most impactful changes in the twenty-first century.

This article reviews developments in globalization in education in the recent past and discusses the challenges and prospects of globalization in education in the future.

Global Standardization

The first major development in globalization and education is increasing global standardization of educational policies, student experiences, and teaching practices. For a variety of reasons to be discussed in this section, education providers, which have typically been local, have engaged in activities that aim to comply with and compete against a global standard, just like their business counterparts, which have worked to develop international standards and compete with each other to demonstrate their ability to produce better quality products with better practices that are more efficient. As a result, global organizations have been established to develop and market standards, organize competitions, and identify good practices.

The Emergence of Global Standards: The Case of PISA

The growth of the Programme for International Student Assessment (PISA) exemplifies the increasing trend of global standardization of education. PISA is given every 3 years in three subjects: reading, math, and science. Each round focuses on one subject. First launched in the year 2000 by the Organisation for Economic Co-operation and Development (OECD), the PISA has become the world's most influential and successful educational assessment program within just over a decade. Since its first round of testing in 2000, the number of participating countries and economies has increased from 32 (28 OECD member countries and four nonmember countries) to 65 in the most recent round administered in 2012. With over 510 000 students taking the test in 2012, the OECD claims it represented "about 28 million 15-year-olds globally" (OECD, 2010).

Technically PISA is a large-scale international test in only three subject areas, similar to the cross-national testing programs that have been in operation by the International Association for the Evaluation of Educational Achievement (IEA) since 1959. By the time PISA was launched, the IEA had already conducted multiple rounds of large-scale studies in mathematics, literacy, science, civic and citizenship, information literacy, including the well-known Third International Mathematics and Science Study (TIMSS) in the 1990s. TIMSS gained so much traction that the acronym was kept but changed to represent Trends in International Mathematics and Science Study. Despite the success of TIMSS in promoting global standards, it is PISA that has established itself as the *de facto* gold standard for both educational quality and global competitiveness.

Global Standard for Economic Competitiveness

PISA scores have been marketed as indicators of the quality of a nation's human capital, hence its economic prosperity in the future. PISA claims to "assess to what extent students at the end of compulsory education, can apply their knowledge to real-life situations and be equipped for full participation in society" (OECD, 2013b). In a research paper published by PISA/OECD, the authors make a direct connection between PISA performance and national economic growth. According to the authors, an increase of 25 points in PISA scores over the next 25 years would result in an aggregate gain of USD 115 trillion in GDP in OECD countries over the lifetime of the generation born in 2010. The gain would be USD 260 if all OECD countries could raise their average PISA performance to that of the best OECD performer, Finland (Hanushek and Woessmann, 2010).

This marketing strategy has been extremely successful in the age of globalization when all nations are concerned about their competitiveness against others. As a result, political leaders and national governments in many countries have accepted PISA as a measure of their future economic prosperity and thus frequently refer to PISA performances in national policy contexts. For example, the former Australian Prime Minister Julia Gillard set the goal for Australia to be placed top five on the PISA ranking by 2025 (Ferrari, 2012). U.S. President Barack Obama called Shanghai's students' top PISA performance in 2009 another Sputnik moment, evoking the launch of the first man-made satellite by the former Soviet Union, as if Chinese students PISA scores meant the same as the science and technological prowess behind Sputnik.

Global Standard for Educational Quality

The idea that PISA is the global gold standard for educational quality has been firmed established. As the standard for educational quality, PISA now commands the attention of world political leaders, media pundits, and the general public, as well as educational researchers. Standings on the PISA ranking have been equated with nations' educational quality. As such countries that have produce high PISA scores have been automatically accepted as having better education quality and those with lower scores lower quality. Governments, education leaders, and the education sector in countries with low performance or a decline have been criticized, while high-performing education systems have been idolized. For example, after students in Shanghai became the number one on the PISA scale, media stories immediately call them the smartest, the best educated in the world. Germany's poor ranking in the first round caused a national uproar. Doubts about the PISA as a gold standard for educational quality are virtually nonexistent as the few reports that do present doubts are drowned in the overwhelming questioning about why some countries have so much better education (Breakspear, 2012).

Such questions result in global idolization of high-performing countries. Since its first round, PISA has created at least two major education miracles: Finland and Shanghai. Prior to its top performance in the first few rounds of PISA, Finland was little known to the rest of the world. But thanks to PISA, Finland has become the Mecca for education reformers, attracting hordes of pilgrims from all over the world eager to learn how Finland has such a high-quality education system. Without the PISA, few would be interested in reading the now popular book *Finnish Lessons: What Can the World Learn from Educational Change in Finland?* (Sahlberg, 2011). Likewise, Shanghai became the new Mecca as soon as it was announced that students from this Chinese city scored number one in the 2009 round. Prominent education researchers in the United States quickly came up with books like *Surpassing Shanghai: An Agenda for American Education Built on the World's Leading Systems* (Tucker, 2011) to encourage learning from Shanghai.

Global Standardization of Educational Policy and Practices

One of the original purposes of cross-country studies was to understand the effects of policies and practices within and across educational systems. Cross-country studies also provide the opportunity for educational policy makers and practitioners to learn from each other. But PISA has pushed such learning to the level of global standardization. Given the belief that PISA marks the potential for economic competitiveness and educational quality, it suggests that whatever factors contributes to PISA scores should become universally accepted benchmarks. As a result there have been global attempts by individual countries, research groups, international consulting firms, and the OECD itself to identify and summarize policies and practices that can be universally accepted as best practices.

The OECD, in connection with Pearson Foundations, for example, produced *Strong Performers and Successful Reformers in Education: Lessons from PISA for the United States*, a book and a collection of video cases (OECD, 2011). McKinsey & Co, the New York-based international consulting firm, summarized the best practices in its report *How the World's Best-Performing School Systems Come out on Top* (McKinsey & Company, 2007). The same firm, using PISA as the primary indicator of education quality, also came up with an influential on teacher quality based on studies of teacher recruitment, training, retention, and accountability in high-performing countries on PISA to offer lessons about how to improve educational quality via improving teachers (Citation). The Grattan Institute, an independent research group in Australia, conducted a study on the high-performing countries in Asia and published an influential report *Catching Up: Learning from the Best School Systems in East Asia* (Jensen, 2012). The OECD has not been hesitant to directly offer strategies either (Bieber and Martens, 2011). Among others, it suggests a focus on social and gender equity; decentralized school management; a cooperative school structure; strong centralize assessment system and accountability measures with high and demanding educational standards (Schleicher, 2006).

The results have been remarkable. PISA has prompted major policy changes in many countries (Breakspear, 2012; Knodel et al., 2013). Many of the changes are strikingly similar: centralizing curriculum and standards making, global benchmarking in curriculum and standards, strengthening testing and accountability measures, and encouraging local autonomy and market competition so as to reach the same outcomes (Breakspear, 2012). The Global Education Reform Movement or GERM described by Pasi Sahlberg (Sahlberg, 2012) is an excellent summary of the global standardization of education phenomenon. In parallel are similar efforts to standardize teacher recruitment, preparation, and incentivization. Students' experiences are also increasingly homogenized globally as countries emulate or attempt to emulate successes of high-performing nations: more time on academic studies and focus on the PISA subjects – reading, math, and science.

Global Spread of Local Standards and Programs

While the PISA is stimulating the evolution of global standardization of education through collaboration among local governments, there is another growing trend of global standardization, that is, the global spread of standards and programs developed for a specific local context. In the age of globalization, as schools, parents, educators, and governments look for high-quality programs and standards, they have started directly 'buying' standards and programs developed elsewhere.

International Baccalaureate

The rapid growth of the International Baccalaureate (IB) in recent years is a telling example. Founded in Geneva, Switzerland, IB was originally developed as "a single program for internationally mobile students preparing for university" by "a group of talented, forward-thinking teachers at the International School of Geneva, with assistance from several other international schools" (IBO, 2013a). At its early stage, the majority of schools that use the IB program were international schools, with a few government schools.

The rapid expansion of the IB did not start after the 1990s. There were only 269 IB programs in 1989. The last decade of the twentieth century saw some acceleration in growth. The number of IB programs increased to nearly 889. The growth skyrocketed in the twenty-first century. In 2012, there were 4231 IB programs in over 140 countries around the world, an astonishing fivefold increase in 12 years (IBO, 2013b). More importantly the IB is no longer a high school program for internationally mobile students. It has become a complete education program for students aged 3–19 years with the original IB Diploma Programme (DP), IB Middle Years Programme, and IB Primary Years Programme that were added later, and the newest addition the IB Career-related Certificate Program. Over half of the IB schools today are not international schools serving mobile students.

In its essence, IB is a curriculum similar to other curricula offered within a local school but it has become a global franchise. As a complete curriculum, carries its own philosophy and standards of education. A school that decides to adopt IB cannot pick and choose what IB courses to offer, but adopt the entire program and of course its standards and philosophy. Students go through the program and complete the requirements following the IB prescription. In other words, students in IB programs all over the world have the same experience, in very much the same way as customers of McDonald's restaurants. In other words, IB is grown from a local school curriculum to a global standard.

The quick spread of the IB in the past decade is largely driven by the desire for global high standards of education, the same that fueled the PISA movement. To many, the IB (and the Advanced Placement or AP) "represent the curricular gold standard for secondary education" (Byrd et al., 2007: p. 7). Governments, philanthropy organizations, schools, and local communities around the world have been eager to promote the franchise of IB and the AP in the hope to upgrade their education to a global standard (Byrd et al., 2007). Tony Blaire, former British Prime Minister, once announced his support to develop an IB DP school in every local authority in England (Abrioux and Rutherford, 2013).

Localization of International Schools

Another burgeoning phenomenon of global standardization is the localization of international schools. Like the IB, international schools were initially established to offer an education to a highly mobile population – children of diplomats, staff of international businesses and organizations, and military personnel stationed away from their country of origin. International schools typically offer a curriculum that bears the standards of their country of origin, or different from the local curriculum where they reside. In other words, international schools are outposts of national education systems in other countries.

International schools have gone through a rapid period of growth and transformation in the age of globalization. "In the past, international schools reflected the process of international migration, with expatriates and diplomats wishing their

children to be educated in systems compatible with those of their home country" (Hayden and Thompson, 2008: p. 9). Hence until very recently the majority of international school students were expatriates. But "Today, locally born residents fill about 80% of spaces in international schools and drive about two thirds of the market expansion" (ICEF Monitor, 2013). The expansion has been astronomical: 153% increase in the number of international schools in just 12 years. At the beginning of the 2012–13 academic year over 6300 international schools were recorded. The number is expected to reach 11 000 by 2020 and will serve over 6 million students (ICEF Monitor, 2013).

The growth of international schools in the last decade has been driven by the same desire to have high-quality education or "a certain dissatisfaction with the quality of the national education offer; the desire to sponsors and families to foster a global outlook that is not tied to a particular culture or education system; and the expressed need to prepare students to live and work in a globalized world" (Hayden and Thompson, 2008: p. 9). An international curriculum is deemed as high standard. "Not only are new schools continually opening, but their ranks also grow whenever existing schools convert to an international curriculum, begin instruction using a foreign language (usually English), or open a satellite campus in another country" (ICEF Monitor, 2013).

The Irony of Global Standardization: East versus West

There are two distinct trends in the globalization standardization movements in terms of the origin of the 'gold standard.' In the mostly government-driven movement inspired by PISA and other international tests, the East, that is, East Asian countries seem to be the source of high-quality education because they have consistently produced high scores. Ironically, the fastest growth of international schools with curriculum standards originated from the West, mostly the United Kingdom and the United States, has been seen in East Asia. Today, over 50% of international schools are in Asia. China, for example, with only 22 international schools just a decade ago, had over 340 in 2012. In Singapore, Hong Kong, South Korea, and China, all with high PISA scores that the West admires, "government funded efforts have resulted in the development of entire international education hubs" (ICEF Monitor, 2013). It seems that the gold standard of education for the East Asian countries is entirely different from what has been identified by the PISA.

Global Enterprising

Globalization has also created the possibility for existing educational institutions and educators to imagine and evolve from local providers into global enterprises. The desire of schools to pursue high-quality education, especially internationally recognized qualifications, presents an attractive market for entrepreneurially minded education entities to export their products globally. The result is the emerging phenomenon of global enterprising on multiple levels: systems, schools, and teachers.

Enterprising Systems

Related to the global spread of local standards and curriculum discussed in the previous section is the entrepreneurial efforts to export educational qualification courses and exams to students and schools globally. Unlike the IB, students and schools do not have to adopt the programs in their entirety. Local schools do not have to change their entire school curriculum, thus making themselves as a retail store of different programs. This flexibility creates a vast market for different programs to coexist and motivates a large of group of players to enter the global market.

National qualification systems that were historically developed to serve their citizens have been exported to other countries. One of the systems that entered the global market earlier is from the United Kingdom. The various versions of its qualifications such as the O-Level, the A-Level, GCSE, and the IGCSE designed for students in England, Wales, and Northern Ireland (Tattersall, 2007) have been used in many commonwealth countries or former British colonies for a while. They have recently entered more countries, even government schools in sovereign countries such as China. What is interesting is that the offerings of the qualifications and supports have become commercial products that schools and students in other countries purchase. As a result, providers such as Cambridge International Examination and Edexcel of the global education business giant Pearson have become global enterprises. IGCSE, for example, was taken by students in 120 countries in 2010.

The Victoria Certificate of Education (VCE), a qualification system owned by the government of the state of Victoria, Australia has been actively marketing the qualifications and licensing it to schools outside Victoria. The VCE is now taught in eight Chinese schools under license through schools in Victoria (VCAA, 2013). Canada is another example. While there is no national curriculum or qualification in Canada to export, education ministries of its seven provinces all accredit offshore schools and offer them the right to teach Canadian curricula and award Canadian diplomas, for a fee. British Columbia even let public "school districts operate as profit-making intermediaries" (Godsall, 2011).

The AP offered by the College Board was originally designed for students in the United States in 1950s, but in recent years it has been expanding its global reach as well. It is not a government-backed program but generally accepted by higher education institutions in the United States. In the last decade the number of non-U.S. students taking the AP increased by four times from around 20 000 in 2002 to over 80 000 in 2012.

Enterprising Schools

Some schools and universities have also taken an entrepreneurial approach to education in the age of globalization. Although still at its early stage, we are seeing a growing trend of educational institutions, both postsecondary and K-12, evolving into global enterprises by exporting their products to other countries. These enterprising efforts take a number of forms, but primarily in the following ways.

Joint Programs: Global Supply Chain

The first form is very much like a global supply chain, that is, the final product, in this case students, is created by different institutions located in different parts of world. Higher education institutions from developed countries have been offshoring parts of the product-making process to other institutions. For example, a university in the United States can have 2 years of the 4 years its degree program requires taught by an institution in India or China. Such joint programs have been extremely popular because it saves the students and institutions costs and resources. In China, the number of such joint programs has grown from 0 in 1990 to nearly 2000 in 2012, not counting those not officially approved by the Chinese authorities. Over 1 million Chinese students have graduated from these programs by 2012.

Independent Campuses: Global Outposts

Another common form is building or renting a campus. Traditional basic education schools such as the Harrow School and the Dulwich College from England have begun their global enterprising journey. In recent years, they have built campus in multiple locations in Asia. The University of Nottingham opened its Ningbo campus in China in 2004. Most recently, New York University opened two campuses, one in Abu Dhabi and one in Shanghai. While the nature of their operations may vary slightly, these campuses are no question examples of these institutions' global enterprising ambition.

Distance and Online: Virtual Campus

Another form of global enterprising is through technology. While distance education programs have been pioneered by dedicated institutions such as the Open University in the United Kingdom, recent technological development has enabled more traditional schools and universities to attract students globally. One of the most amazing developments is Massively Online Open Courses (MOOCs). Starting in 2011, a number of well-financed consortia of prestigious universities in the United States have begun to offer free online courses to students around the globe. While it is too early to know how MOOCs may or may not affect higher education or K-12 education around the globe, it is clear though that traditional educational institutions can have access to a global audience without being physically present.

Global Migration of Students

Students pursuing education in a country where they were born is not a new phenomenon but globalization has certainly enabled more students to do so in recent years (She and Wotherspoon, 2013). As a result, international students are one of the fastest growing parts of the global education system. "The number of students enrolled in tertiary education outside their country of citizenship increased more than threefold, from 1.3 million in 1990 to nearly 4.3 million in 2011, representing an average annual growth rate of almost 6%. This is a greater increase than the overall rise in tertiary enrolments globally," says to an OECD report in 2013 (OECD, 2013a: p. 1).

Globalization is unquestionably one of the primary drivers behind the rapid growth. First, the increasingly globalized and competitive world places new demand on skills and qualifications, placing more value on tertiary education obtained in countries which have traditionally been viewed to have better universities and colleges. It is thus no surprise to see the Western developed nations that have the reputation of offering excellent higher education as the top receiving countries. In 2011, 77% of international students were studying in OECD countries, with over half of them in the top five hosting countries: the United States (17%), the United Kingdom (13%), Australia (6%), Germany (6%), and France (6%) (OECD, 2013a: p. 1).

The second reason that globalization fuels the growth of international students is lowered costs and barriers to study abroad as well as rising income. China, for example, did not begin to send any students to the Western countries until 1978. But today it has become the largest source of international students. In 2011, China had over 700 000 students studying abroad, 85% of whom in OECD countries (OECD, 2013a). This is largely because of China's political change after the Cultural Revolution and the rising middle class as a result of its participation in the global economy.

These two reasons, if they continue to be true, will greatly change the landscape of global student migration in the global education market. First, if and when high education system develops in developing countries, they will become competitors to the existing providers. For example, the number of foreign students in Korea has increased over 17-fold between 2000 and 2011, while the share of international students in the United States dropped from 23 to 17% during this period (OECD, 2013a). It is likely that China will become the next major player in attracting international students. China has already seen exponential growth in the number of overseas students over the last decade. In 1999, about 52 000 students from 166 countries studied in China; the number increased by six times to over 320 000 in 2012 (China Association for International Education, 2013). Likewise, as their economies develop, we can expect more international students from countries that are not major sources of international students. The next likely group may be from Southeast Asia, Latin America, and Africa.

Global student migration is not only limited to higher education. Although the number remains small, students at the basic education level have begun to study in other education systems.

Global Citizenship: Globalization's Demand on Education

Globalization places new demand on education and one of the primary challenges is to change its orientation from preparing only local and national citizens to global citizens. Global citizens must be globally competent. Global competencies have no universally accepted definition but it generally include "the skills, knowledge, and attitude to work effectively in our increasingly interdependent world," according to the

University of Wisconsin Task Force on Global Competence (University of Wisconsin-Global Competence Task Force, 2008, p. 3). The task force further states: "Foremost amongst these 'global competencies' are the abilities to communicate effectively across linguistic and cultural boundaries, to see and understand the world from a perspective other than one's own, and to understand and appreciate the diversity of societies and cultures. Students need to appreciate the interdependence of nations in a global economy and to know how to adapt their work to a variety of cultures" (University of Wisconsin-Global Competence Task Force, 2008, p.3).

Fernando Reimers, a Harvard University education professor, recently offered a similar definition that includes three dimensions: the affective dimension, the action dimension, and the academic dimension. The affective dimension is also called the ethical dimension, which refers to "a positive disposition toward cultural differences and a framework of global values to engage difference." The action dimension is also the skill dimension, which primarily means the "ability to speak, understand, and think" in a foreign language. The academic dimension has to do with academic knowledge of the world, hence also referred to as the disciplinary and interdisciplinary dimension, and that includes "deep knowledge and understanding of world history, geography, the global dimensions of topics such health, climate, and economics, and the process of globalization itself" (Reimers, 2009).

Consistent across most definitions of global competence is the issue of others. The hallmark of globalization is the death of distance, which has brought 'others' previously separated by distance into our lives and how to view them, interact with, and live with them has become a significant issue facing all of us. Thus the foundation of our ability to live in the global world is the knowledge, perspectives, and skills required to live and work with people who are different from us culturally, linguistically, economically, and religiously (Zhao, 2009b).

Global competence and global citizenship have been identified by many international organizations and governments as crucial for our children to succeed in the age of globalization. In Australia, for example, Asia literacy, which is part of global competency in that it reorients Australian's focus to Asia, a more important part of the globe than their traditional partners – Europe and the United States, has been recognized as essential for young Australians to succeed in the future. In the United States, the Asia Society and a host of other organizations have been working promoting global competencies in schools (Asia Society, 2008). The increasing number of international students and international education programs represent the strong interest of students in developing countries to gain global competency. However sadly, global competency has not factored in as major component of education provided in most schools around the world.

Conclusions: Major Themes and Issues

Globalization in education is still relatively new and constant evolving phenomenon. The article provides preliminary observations of some recent developments, which by far do not capture the dynamic and complex possibilities globalization may bring to education. However, even this preliminary review offers some intriguing and challenging themes and issues brought about by globalization.

Homogenization and Diversification

It seems clear that globalization has brought many attempts by national authorities and international organizations to standardize education. Thus it warrants concern about possible global homogenization of education. Given the vast diversity and inequality that exists around the globe, a globally homogenized education may not serve everyone well. Moreover, although we have entered the age of globalization, when it may work better for nations to develop a diversity of talents instead of competing with each other in the same domains, nations in general seem to be stuck in the Cold War age by engaging in an education arms race through international tests. However, globalization has enabled more grassroots educational exchanges, which makes it possible for a more diverse education scene in the world. Furthermore, what is paradoxical is that although nations are all working hard to out-educate others, there is tremendous interest in collaboration and exchanges of educational ideas, strategies, and programs among different countries. No country is hiding their education secretes from each other.

Educational Sovereignty

Historically education, at least that offered by government schools, is considered a national matter. However, globalization results in "the erosion in the autonomy of the nation-state in all matters, including educational policy matters" (Burbules and Torres, 2000: p. 15). As shown in this article, there are significant growth of importing and exporting of education standards, content, and qualifications among countries. Such exporting and importing poses serious challenges to countries sensitive to the issue of educational sovereignty. For example, China still would like to maintain control of education for its citizens, thus it still does not allow its citizens to attend international schools in China. It also maintains control of international joint education programs by requiring prior approval for overseas educational programs to operate in China. At the same time, in the interest to bring high-quality education and stimulate educational innovations, it seems necessary to allow a variety of successful programs, regardless of their place of origin, to enter national markets. Countries will have to work on this issue in the coming years, if not decades.

Brain Drain, Brain Gain, and the Flight of Talents

Developing countries have traditionally been concerned about losing their talents when their students go for advanced studies in other, mostly developed, countries, hence the issue of brain drain. In the age of globalization, this issue has changed. Increased mobility as well as technology enables high-level talents to move around different locations with ease and work remotely. Additionally multinational corporations recruit and deploy talents globally. Thus developing countries, should

they desire and are able to provide the necessary conditions to attract talents, they cannot only have talents originally from their own country but also talents from around the world to work for them, hence changing brain drain to brain gain because these talents have received advanced education that their countries may not be able to provide. The issue is who can attract the best talents, not who can educate the best talents.

A Final Word

Education will surely change in the age of globalization. The changes will pose tremendous changes to nations at both the policy and practice levels. But today, fundamental changes have not been instituted yet. What has happened so far is not transformational in that education is still conceived the same way as it was a century ago: a group of students working with one adult (the teacher) belonging to an institution that educates and certifies the education. It is still driven by institutions. A true revolution will be a new paradigm of education in which students are the driving force and organizer of education. Globalization certainly presents such possibilities.

This article is a revision of the previous edition article by B. De Sousa Santos, volume 9, pp. 6277–6284, © 2001, Elsevier Ltd.

Abstract

Law's role in globalization is often misunderstood, mainly with respect to whether 'the global' is its own distinct and unified field. To a large extent, this misunderstanding reflects the influence of neoliberalism, some versions of which treat globalization as a function of capitalism (thereby relegating it to the preserve of economics). Accordingly, one might not think that law has much to do with this phenomenon, beyond stepping out of the way, except where law contributes to the creation of markets and to ensuring that they function efficiently. But the reality of globalization challenges such formulations, and this article argues that law has an important role to play. The contexts in which law is relevant reflect the great diversity of relationships, circumstances, and legal arrangements under which globalization now develops. This article will examine three such contexts. The first deals with multilateral treaties, the second with corporate social responsibility and voluntary regulation, and the third with domestic law.

Introduction

Law's role in globalization is often misunderstood, mainly with respect to whether 'the global' is its own distinct and unified field. To a large extent, this misunderstanding reflects the influence of neoliberalism, some versions of which treat globalization as a function of capitalism (thereby relegating it to the preserve of economics) (Harvey, 2005). Such a formulation leaves little room for law, except in relation to international law and such 'global' institutions as the International Monetary Fund (IMF), the World Trade Organization (WTO), and other legal arrangements primarily associated with the liberalization of trade. From this standpoint, one might imagine that globalization is all about competition – a competition for markets and investments that is global in scale and increasingly intense as markets expand. Accordingly, one might not think that law has much to do with this phenomenon beyond stepping out of the way, except where law contributes to the creation of markets and to ensuring that they function efficiently.

But the reality of globalization challenges such formulations. Law has an important role to play, particularly in contexts in which economic activity generates human rights questions, such as child labor (de Feyter and Gomez Isa, 2005; Hallo de Wolf, 2011; International Labour Organization, 1999; Roe v. Bridgestone, 2007). This article discusses law's prominence in the creation, implementation, and contestation of globalization. The contexts in which law is relevant reflect the great diversity of relationships, circumstances, and legal arrangements under which globalization develops (Calliess and Zumbansen, 2010; Kingsbury et al., 2005). This article will examine three such contexts: multilateral treaties, corporate social responsibility (CSR) and voluntary regulation, and domestic law.

Globalization is embedded in our institutions – domestic and international, public and private, by virtue of legal arrangements (legislation, agency regulations, contracts, etc.) that draw global 'forces' into everyday life, and vice versa. It is not a unilinear process or geography 'out there,' but a dynamic relation across multiple regimes of public and private ordering (Aman, 2001a, 2004, 2006; Delbrück, 1993). Globalization is subject to a wide array of influences and control, and yields pervasive social effects – some of them broadly homogenizing, some of them diversifying in highly specific ways (Aman, 2009; de Sousa Santos, 2006; Harvey, 2006; Sassen, 2003). Understanding the relationship of globalization to law requires analysis of the interactions of markets, rights and bodies of law at all levels of government, domestic and international, as well as diverse processes of governance that involve norm creation, enforcement, and adjudication by state and nonstate actors alike (Calliess and Zumbansen, 2010; Halliday and Carruthers, 2009).

Moreover, globalization is neither external and superior to national states, nor primarily state centered. The essence of globalization is its denationalizing effect (Sassen, 2006; Delbrück, 1993). Thus it has been said that, "Globalization … may be defined as the process of denationalization of clusters of political, economic, and social activities" (Delbrück, 1993). In a globalized world, various nonstate actors, including multinational corporations (MNCs), play key roles precisely because they are not bound to any one jurisdiction (Backer, 2011). Globalization includes global and regional institutions such as the WTO and the European Union, but globalization is also a domestic phenomenon, driven by private actors and local law.

While this article is concerned with some phenomena that are global in the geographic sense, this is only one subset of our concerns with transnational law (TL) more generally. For example, there are some issues such as ozone depletion (see *infra*) that are truly global (i.e., affecting the whole world), but many pressing transnational issues do not involve universal or planetary stakes. Indeed, there are many domestic contexts in which law may properly be understood as 'transnational' – that is, in its functioning across bodies of law, public and private, domestic and international, rather than in a particular geography or international field. TL potentially encompasses legal relationships involving domestic and international law as well as private ordering

involving a host of nonstate actors who operate transnationally. The complex sociopolitical interrelationships resulting from these interactions affect institutions and individuals in a variety of ways at home and abroad (wherever these may be). Law features in all of these arrangements, highlighting the pluralism and polycentrity of law's 'many rooms' (Galanter, 1981). States play important roles in global governance issues, but so does the private sector – the latter becoming increasingly important even rivaling or substituting for state powers in some contexts (Backer, 2011).

The emergence of a global private sector has been accelerated by technological advances in high-speed worldwide communication (including transfers of funds). The mobility of capital has been especially important to the development of modern 'global' firms and their prominence in global capitalism (Harvey, 2010; Strange, 1997). Private decisions involving, for example, production, finance, and investment occur increasingly free of direct, individual state involvement. Moreover, MNCs may shop around the globe for the locations most favorable to their interests. Transnational corporations thus decide where it is most cost effective to locate various activities in the sometimes long value chains connected with the production and marketing of their goods and services. They may locate Research & Development in one country, component assembly in another, final assembly in another, and distribution networks in yet another. They also decide how much to customize the globally conceived product for local markets (Dunning and Lundan, 2008). The General Agreement of Tariffs and Trade and other multilateral agreements facilitated trade in goods; a substantial portion of world trade today takes place between and among divisions of the same company doing business in various locations around the globe (Dunning and Lundan, 2008). Trade intensifies other transnational phenomena. Migration often follows the itineraries of trading relationships as well as military engagements (Sassen, 1998; see also Mosk, 2005).

These factors do not mean that states are no longer important as influences on these businesses or that they are powerless to affect environmental problems on a global scale. Still, the regulatory role nation-states play is substantially different than it was in the past, because deregulation, privatization, and market-oriented regulatory approaches are more prevalent than they were a generation ago (Akech, 2009; Aman, 1998, 2001b; Cerny, 1990; Prakash and Hart, 2000). For other reasons, too, the efficacy of states is becoming more limited; for example, problems such as the environment, security, or some areas of public health cannot be resolved effectively by the way of individual nation-state action alone. The political networks involved in these and other issues (such as climate change, ozone depletion, the destruction of the rainforest and other biohabitats, and human rights generally) transcend nation-states and state institutions. That said, global problems do not always demand exclusively global solutions; local engagement remains relevant (Myint, 2012; Ostrom, 2010; Valverde, 2009). For example, as we shall see, infra, the Montreal Protocol dealing with ozone depletion benefited considerably from the domestic laws and politics in the United States that preceded its drafting. New bodies of TL are developing to deal with problems that are neither wholly domestic nor comprehensively global – sometimes working through domestic law, sometimes creating new authorities and powers (Cole, 2011; Paavola, 2011; Ostrom, 2010; Koh, 1994).

Transnational Law

The term 'transnational law' was coined by Phillip Jessup in his seminal lecture in 1956 entitled *Transnational Law*. In that lecture, he claimed that TL includes "all law which regulates actions or events that transcend national frontiers. Both public and private international law is included, as are other rules which do not wholly fit into such standard categories" (Jessup, 1956). TL develops in the gaps that exist between states but also emerges in other contexts. For example, it involves supply contracts between and among MNCs, *lex mercatoria*, and other bodies of law developed by nonstate actors wholly outside or sometimes in the shadow of the state (Shaffer, 2013; Mattli and Woods, 2009; Zumbansen, 2006; Teubner, 1996, 1987). Laws created by worldwide sports federations like the International Olympic Committee or the Fédération Internationale de Football Association – world soccer's governing body – the best practices of various global industries, international standards (Mattli and Buthe, 2003), and voluntary rules including corporate codes of conduct and other modes of self-regulation also fall within the purview of TL (Blackett, 2001; Cutler, 1999; Compa and Hinchliffe-Darricarrère, 1995). In short, the term 'transnational' refers to pluralistic, multicentered, and dynamic processes involving interrelationships among states and nonstate entities, whether across national boundaries or within them.

Depending upon the context involved, TL may involve domestic law, international law, some form of voluntary regulation, or various combinations of all the three. Increasingly, TL involves hybrid forms of power sharing among public and private actors. These hybrid arrangements are one prominent result of various contemporary forms of delegation of state power. Sometimes state power is delegated 'up' to an international entity such as the WTO; other times there may be a delegation or devolution of state power 'downward' to a substate jurisdiction, such as in a federal system with its member states. States also delegate power horizontally to private entities – for example, when a governmental agency outsources its regulatory functions to a private provider of these services.

Given the horizontal aspects of state delegations of power, and the fact that states are limited in their regulatory reach by their own jurisdictional limitations, it is not surprising that, increasingly, voluntary regulation becomes one of the main ways in which law develops outside of the state (Backer, 2011; Blackett, 2001). Moreover, by partnering with transnational corporations, states are able to achieve more in certain arenas than if they operated solely on their own. Corporations' powers as transnational legal actors may be significant, especially given the increasing competition between and among states with respect to attracting and retaining private investment. The influence of transnational corporations in relation to regulatory and tax issues encourages the flow of power from states to market actors and back again. But such shifts are not automatic.

They occur through legislation and regulatory and deregulatory procedures, and reflect the impact of domestic, state-centered law and politics on international and domestic fronts (Aman, 2001b, 2004, 2008; Freeman and Minow, 2009).

For all of the reasons discussed in this section, understanding how denationalizing processes work is an important part of understanding law's role in relation to globalization.

Denationalization

The denationalizing processes associated with TL are integral to the decentering effects of globalization, understood more broadly. Pollution, drug trafficking, terrorism, and global investment opportunities involve diverse challenges, but the processes involved in creating, implementing, and adjudicating the rules are alike in not necessarily being bound to or by any one particular jurisdiction. One way for states to regulate such activities successfully is to cooperate on a long-term basis, and this usually means pooling their sovereignties in some way (Delbrück, 2002). Such pooling may take the form of a multilateral treaty or a delegation of power to an international organization such as the WTO. The pooling of sovereignty and the delegation of state power to international bodies inevitably create denationalizing effects, as new actors bring their policy perspectives and national interests into the negotiating arena.

Similarly, markets, capital, technology, ideas, and culture – like people – are mobile, not necessarily tied to jurisdictional boundaries (Appadurai, 1990). Economic globalization developed around a commitment to the free flow of investment capital across borders. It previously had been common for states to try to regulate international capital flows, but unregulated capital flow has been synonymous with globalization for decades. Currently, however, new regulatory initiatives are emerging in some states, and their potential value as a means of managing volatility has been recognized by the IMF (Klein, 2012; International Monetary Fund, 2012). These regulatory efforts are inevitably restrained by both the inherent difficulty of unilaterally regulating cross-border activities and the potential risk of repercussions.

The very nature of certain kinds of global issues may obviate state action or bypass states altogether. Globalization thus draws attention to processes that are essentially deterritorialized and often independent of states. This is especially true of economic, social, and cultural processes, but it also includes various law and norm-creating processes that may develop among private actors (Shaffer, 2013; Abbott and Snidal, 2009). Private entities themselves may make the law they believe is necessary to govern their activities in complex transnational situations. TL can be and often is made by states, but it can also be made outside the state or, to the extent private lawmaking is influenced though not necessarily governed by state law, it can be made in the shadow of the state (Abbott and Snidal, 2009; Calliess and Zumbansen, 2010; Kahler and Lake, 2003; Shaffer, 2013). Such *de facto* delegations of state power to the private sector are key features of globalization.

Recognizing globalization as intersecting and multilayered fields of transnational actors, both inside and outside the state sphere, yields a richer and more dynamic account of the multiple legal relationships involved in the development and application of TL.

To illustrate these various aspects of TL, this article now turns to the three contexts in which TL is made, through a series of case studies. The cases illustrate treaty processes, voluntary regulation, and domestic law. All three cases involve the United States in some way – not because American experience defines globalization, but because the variety of 'angles' on the 'Americanness' in these scenarios is illustrative of diverse modalities of TL that are more broadly relevant.

Transnational Legislation: Multilateral Treaties and the Global Environment

Quite apart from issues facing multiple jurisdictions, some global issues are the result of activities, interests, or problems connected to specific transnational places or spaces over which no one state has control – such as the oceans (Law of the Sea) or outer space or the Arctic Circle. One example of this phenomenon involves the ozone layer in the stratosphere of the Earth. To respond to this problem, many nations developed the Montreal Protocol to reduce chlorofluorocarbon (CFC) emissions from around the globe, emissions that were causing the ozone layer to rapidly deteriorate. Ozone depletion presented global actors with a new and daunting set of challenges, which required innovation as well as adherence to traditional treaty processes.

Ozone depletion represented a global commons problem with a clearly defined source, but a less-defined solution. The Montreal Protocol's negotiators confronted a problem affecting a resource that no one state could effectively regulate – the Earth's atmosphere – yet the destruction of which would negatively affect everyone. But international standards without domestic support would accomplish very little.

In the case of the Montreal Protocol, domestic law and politics played an important role in creating the domestic legal and political environment necessary for the United States to pursue such a treaty in the first place. Moreover, nation-states were not the only players. Various nonstate actors played crucial roles in devising the regulatory approaches ultimately adopted. Moreover, the politics necessary to accomplish these goals was fueled not only by technological innovation and the prospect of new markets for new products, but by the ability of science to dramatize the human stakes involved for everyone, regardless of where they lived, and a politics willing to accept this science (Benedick, 1998).

Domestic law laid the groundwork for the treaty process. In the United States, the Congress had passed legislation to curb domestic use of CFCs (Toxic Substances Control Act, 1976). The participants of the Montreal Protocol came to the table from markedly divergent viewpoints – several represented constituencies that were heavily invested in the production and use of CFCs. Those involved in the process agreed that science offered the possibility of an analysis of environmental problems that could be shared by all countries. This was essential. Reliable scientific evidence helped to unify the international community around a political solution (Aman, 1992; Benedick, 1998). In 1987, the Montreal Protocol – a binding multinational treaty

regulating CFC consumption – was signed (Montreal Protocol on Substances That Deplete the Ozone Layer, 1987).

As Benedick details in his analysis of the treaty process and its aftermath, it was not just science – industry leaders in the United States and abroad (Europe especially) carefully matched each other's actions in gradually 'disarming' their industries of CFC production, and substituting ozone-friendlier substitutes. For example, in September 1988, the US Alliance for Responsible CFC Policy announced that it was in favor of the CFC phaseout, and the UKs Imperial Chemicals Industries followed suit soon thereafter. Industrialists in the Federal Republic of Germany, Japan, and other major industrial nations, seeing the path set forth by the British and Americans, began to draw down their CFC use as well. This industrial cooperation strengthened the signatories' momentum going into the Protocol negotiations, and contributed to the relatively seamless implementation process that followed the signing of the Protocol.

In short, a primary reason for the Protocol's success was that the problem and solution that the Protocol sought to address was clear: (1) this precise phenomena; (2) caused by these specific chemicals; (3) with these demonstrated risks; (4) affecting all people; (5) could be remedied by these specific actions, with available substitutes; (6) over a specific timeline (Sunstein, 2006; Benedick, 1998; Aman, 1992). The negotiators had a comprehensible, focused, and universally applicable problem before them. The ozone depletion threat was truly global in terms of the scope of its potential consequences, as well as the contributing factors to the problem. The Montreal Protocol was a success story when it comes to the creation and implementation of this type of TL, but the almost 'perfect storm' nature of the elements of its very success are illustrative of why such cooperation among multiple states at the global level is, and is likely to remain, so rare. Global warming highlights the immense difficulty of crafting a multilateral treaty when nations are unable to reconcile divergent interests, let alone agree on the underlying science involved. Nevertheless, the Montreal Protocol is a model of one kind of intersection of globalization and law, albeit one not easily duplicated.

TL in the Shadow of the State

The polycentric nature of global environmental problems and the different interests that states bring to their resolution are not confined to environment and global commons issues. Discussion in this section moves to another context in which they arise – in human rights questions involving, for example, labor relations and conditions of employment. Global uniformity in such matters is highly unlikely for a number of reasons, including the variation that exists among states in their economic, political, legal, and cultural orientations toward providing for social welfare, as well as their capacity to regulate employers and supply contractors who seek a competitive advantage in a low-wage workforce (Harvey, 2010).

Beginning as early as the 1960s, responding to tax and regulatory incentives, wage differentials, and other factors, Western companies began to close their domestic factories and outsource manufacturing abroad in certain industries (Goldin and Katz, 2007). Companies outsourcing labor no longer had to deal directly with a workforce. Transnational supply chains created by contract began to substitute for local labor forces governed by national and state labor laws. Many of the jurisdictions to which labor was outsourced either had no effective labor laws in place, or no effective means of enforcing the laws in place (Sum and Ngai, 2005).

In the 1970s, a number of external codes of conduct were promulgated by major international agencies, such as the UN, the Organisation for Economic Cooperation and Development, and the International Labour Organization (Compa, 2008; Organisation for Economic Co-operation and Development, 2008; International Labour Office, 2006). They set forth various declarations and guidelines to protect workers' rights. They were external codes because they were created outside the corporations involved; their value was largely symbolic but they were significant nonetheless (Compa, 2008; Perez-Lopez, 1993; Sullivan, 1983).

CSR embodied in corporate codes of conduct developed internally by the corporations themselves began in earnest in the 1980s and early 1990s when firms such as Nike, Reebok, Levi Strauss, and others produced codes of conduct internally that were designed to regulate the supply contractors in their respective global production chains (Compa, 2008; Compa and Hinchliffe-Darricarrère, 1995; Perez-Lopez, 1993; Levi Strauss & Co., 1992; Swoboda, 1992). Moreover, Western media outlets began to run stories calling attention to, for example, the extensive use of child labor or other inhumane labor conditions found in foreign factories manufacturing sneakers and apparel for these and other companies.

There has been progress in the promulgation of meaningful supply chain management and regulation on two fronts in particular. The development of these CSR codes is becoming more democratic in the sense that companies, unions, human rights groups, and community organizations are increasingly all involved in the development phase (Fransen and Kolk, 2007). This new generation of codes is called 'multi-stakeholder' codes (Compa, 2008). At the same time, these new codes have monitoring mechanisms that rely on outside parties, beyond the corporation itself (Compa, 2008; Keller, 2008; Fransen and Kolk, 2007). Monitoring groups include groups such as the Fair Labor Association (FLA), which is a coalition of universities and nongovernmental organizations, Social Accountability International, and other third-party monitors that add independence and legitimacy to the auditing process (Compa, 2008; Keller, 2008).

Self-Regulatory Processes

In these contexts, we observe a very different lawmaking dynamic than the one that drove the Montreal Protocol. The labor conditions that came to the attention of the general public were driven not by science, but by worker fatalities.

The legitimacy of a firm or an industry's attempts to make and enforce their own law may turn on the degree to which those laws and the processes resemble those of the states in which they operate (Ochoa, 2011; Scott, 2010); however, neoliberal reforms do not automatically translate into traditional forms of government regulation (Shamir, 2005). Indeed, as Shamir writes, "[s]uch a theory must come to grips with, and identify the pitfalls of, working within the non-governmental organization institutional paradigm, because the latter is heavily biased

toward the corporate hegemonic model of organization and implementation" (Shamir, 2005). As a consequence,

> [We] must also worry about the way the perceived grievances of oppressed, marginal, and exploited populations…are transformed into a meaningful political and legal voice by relatively affluent and secured…experts who often speak the language of and deploy the instruments of hegemonic rational organizational and managerial systems characteristic of contemporary capitalism…. [T]here seems to have emerged a hegemonic cultural-institutional model concerning the 'right way of doing things'. This right way of doing things purports to be divorced from actual substance as it deals with models, blueprints, protocols, procedures, key words, and key concepts alone. (Shamir, 2005)

CSR is not a substitute for domestic law and law enforcement, nor is it a substitute for collective bargaining. TL made primarily by private actors and traditional state law are as likely to diverge as converge.

The Domestic Face of Globalization and the Globalizing State

Domestic legal systems are not just affected by global processes; they are embedded within them, and integral to them. This fact merits far more attention than it is generally accorded by globalization scholarship; however, it is crucial to understanding the relationship of globalization and law. By looking at globalization's domestic side, we can appreciate both the effects of globalization on domestic institutions as well as the potential effects of domestic institutions, especially legal institutions, on globalization. The domestic side of globalization may be counterintuitive for those who imagine globalization primarily in terms of a free-flowing private sector. However, the interplay between the globalization of capital, TL, and domestic legal processes is central to our topic.

My term for this complex and dynamic relationship between globalization and domestic law is the 'globalizing state' (Aman, 1998). The globalizing state is characterized by a fusion of public and private values, rhetorics, and regulatory practices (including privatization and deregulation). The fusion is itself integral to the interdependence of global and local economies. Privatization is both the engine and the outcome of that interdependence, increasing the exposure of the state to economic and political pressures that in turn tend to accelerate globalization, since private actors fully exposed to the global economy are now charged with carrying out delegated state tasks.

The global political economy places great pressures on all entities, public and private, to be cost effective. In the United States, this has further encouraged delegations of power to the private sector. Given the role that the public/private distinction plays in US administrative law, the globalizing state is one in which privatization tends to correspond to a democracy deficit (Aman, 2004). In lieu of public debate within the institutions of government, privatization favors other arrangements less likely to be transparent and accountable to the public, and less exposed to competing noneconomic value regimes. At the same time, the pragmatics of globalization make privatization the critical terrain in which a new public domestic law might respond to the democracy deficit.

Privatization in the public sector should be understood as a principal effect of globalization as it has been experienced in the United States. Privatization is not merely one means among others for making government more efficient or for expanding the private sector. Nor is it just an expression of current political trends as the regulatory pendulum swings from liberal to conservative. Rather, the increasing reliance on what is commonly referred to as 'the new governance' (Salamon, 2002) is indicative of recent transformations in the relationship between the market and the state itself – transformations that are inseparable from global economic competition and other forms of interdependence as these have developed in recent decades (see Stewart, 1993).

Marketizing Social Services

Outside of the legal spheres referenced above (treaties and corporate codes), the primary area in which law is involved in globalization is in the administrative transfer of state functions to markets. 'Privatization,' 'downsizing,' 'outsourcing,' 'contracting out,' and other forms of marketization are properly considered among the dynamics of globalization, once these are understood in context. The Reagan-era deregulatory reforms that set in motion the pervasive marketization of social services and other government functions in the United States were undertaken to improve US economic competitiveness at home and abroad. The pervasive neoliberalization of certain state functions in the United States and elsewhere in recent decades is inseparable from the development of globalization. National states – like corporations – 'function' in relation to maximizing their competitive advantage globally. This makes for what might seem like 'strange bedfellows' between the domestic and the foreign. In this section, I turn to the marketization of social services to emphasize these little-recognized but important connections.

Marketizing social services became politically popular as electorates became newly aware of global economic competition in the 1980s and 1990s, resulting in major changes in both the idea of 'the public' and the way the public sector functions in American life. The main regulatory reforms in ascendancy today consist of various forms of deregulation, privatization, outsourcing, and public/private partnerships – with the private sector often performing tasks once reserved primarily for government (Kamerman and Kahn, 1989). Indeed, the use of the private sector to deliver what once were governmentally provided services is a common form of privatization. Private contractors are pervasively involved in government functions, from military support to social services and myriad other roles. The primary governance tool in these cases is the contract. In the United States, for example, the management of prisons has been increasingly outsourced to the private sector at both the federal and state levels. Private providers also now commonly handle city services such as garbage and snow removal, and private entities in some states carry out various aspects of welfare administration, such as eligibility determinations (Aman, 2013, 2001b; Michaels, 2004; Bezdek, 2001).

Some forms of privatization result from administrative action; others derive from legislation. The legislature may, for example, sell off a governmentally owned entity to private parties, as was common in Europe in the 1980s. Like the deregulation that results from the wholesale statutory repeal of

a regulatory regime, the market in these instances is intended to replace the government completely when government-owned assets are sold to private buyers. Whether privatization takes place administratively or via statute, it is the context of these reforms that makes such domestic legal activity integral to globalization – just as in different but related ways corporate legal activity may make firms 'global.'

Understanding the role of domestic law in the current global environment enlarges the scope for comparison at the same time that it requires us to take into account the specifics of localized differences, as these are also meaningful. Globalization is deeply embedded within domestic institutions – both public and private – as ideas, relations, interests, and effects. This situation poses both opportunities and constraints on the relevance of law and the potential for law reform, especially as affecting vulnerable populations (Aman, 2009, 2013). Globalization is not just a top-down affair.

In the United States, recent developments in the social service sector illustrate the integral relationship of domestic law and globalization. These include welfare reform (disencumbering the federal and state treasuries), prisons (privatizing in the interest of efficiency), and immigration (setting checks on access to labor markets and social services). These rationales are, of course, highly politicized, but this does not negate their relevance as evidence of a relationship between domestic law (in these examples, Congressional legislation) and globalization. These and other areas of market-driven reforms reflect a particular conception of globalization as global economic competition (Aman, 2004). Along with other aspects of security more obviously linked to the global (e.g., domestic counterterrorism measures), privatization of social services is a primary zone where we can expect to find active channels between global and domestic legal activity and their associated purposes.

For example, welfare eligibility in many states increasingly depends upon judgments rendered by multinational companies whose mandate is to trim the rolls by depersonalizing eligibility and claims processes. Prisoners held in privately managed facilities are subject to companies' business interests and their need to satisfy their shareholders (Aman, 2005; Dolovich, 2009). Some states are eager to compete in the global economy by attracting the new investment and jobs associated with private prisons to their jurisdictions (Aman, 2013). A domestic perspective on globalization draws attention to the fact that the firms to which this work is outsourced in the welfare and prison contexts are MNCs that operate around the world (Bezdek, 2001; Fulcher, 2012; Raher, 2010; White, 2001). The expertise that these firms develop internationally in such public–private management arrangements can accelerate pressures for privatization at domestic and international levels. Immigration – conventionally debated as a border issue – is also a domestic 'front' of globalization. Immigration is in some ways a subset of the broader debate over welfare, as some of the problems facing immigrants are also the problems of the working poor and other populations at the social margins who are particularly reliant on social services (Aman, 2008, 2013; Aman and Rehrig, 2011; Gustafson, 2011; Michaels, 2004). But it is not just the role of multinational firms that make these sectors 'global'; rather, the pervasive formulation of the relationship between service providers and consumers in terms of economic efficiency renders state–individual relations generally as fundamentally economic in character.

The new relationships between private and public actors created by the marketization of welfare, borders, and prisons teach us important lessons about the domestic fronts of globalization and – in that light – we may see the potential for new kinds of law reform that can correct the limitations of a binary conception of law and markets referenced at the outset. Looking ahead, a role for law might be in the development of infrastructures for reforms – for example, contributing to the development of new forums for deliberation and stakeholder participation in relation to decisions regarding whether and how to outsource.

Conclusion

The changes in the world's political economy generally known under the rubric of globalization are fundamentally and simultaneously both structural and political in nature (Aman, 2004). Understanding law's role highlights the diversity of actors and interests involved, as well as the prominence of innovation, improvisation, and a host of ad hoc arrangements in TL – within states and beyond them. TL also highlights the broadening of economic and political networks across institutional and community lines, the technology-driven capacity for rapid change and response to change, and the growing powers of nonstate actors who operate simultaneously in multiple jurisdictions within and across national boundaries, and between public and private sectors. By associating competitiveness with national security, the rhetoric of global competition may sustain the impression that national states can be understood apart from globalization; however, attention to law's nature, sources, powers, and limits in relation to globalization compels a reassessment of such claims. The benefits of such reassessment include a more nuanced understanding of the heterogeneity within globalization, as well as a clearer appreciation of both the specificity of 'global' effects and the global significance of localized movements of protest or reform.

The three contexts considered in this article show some of the many complex ways that TL is both a source and effect of globalization. They represent three perspectives, seen from starting points in state lawmaking, private enterprise, and social security. However, these standpoints are not fixed; each is necessary to understanding the others. For example, the treaty process – though state driven and culminating in a multilateral treaty with global coverage – could not have developed but for the politics developed at the domestic level and domestic laws that made global negotiations feasible. Moreover, private players also played a crucial role in the process, incentivized by the prospect of new markets for new environmentally friendly substitute products. Public and private actors were able to utilize international and domestic law along with markets to reach a successful conclusion.

The importance of domestic law as a crucial component of globalization cannot be overestimated, especially when states privatize administration and services for reasons of economic competitiveness. It may seem obvious that they should do so;

however, that this should be a common sense notion is itself indication of the extent to which global competition has been normalized as the presumed context of public administration. Privatization of prisons and the marginalization of immigrants are integral to the global context in which they occur.

Law's adversarial process and its essential qualities of collaborative contestation remind us of law's potential relevance in the future development of globalization, as well as in relation to current models of globalization beyond the neoliberal one that predominates today. Law has an important role to play in supporting novel stakeholder partnerships and protecting the floor under social security – perhaps something of the reembedding of the market in society envisioned by Polanyi (1944). Critical reactions to the current politics of austerity around the world draw attention to the legal forums already in existence as arenas for experiments with pragmatic and flexible approaches to balancing efficiency and fairness (de Sousa Santos, 2007, 2008; de Sousa Santos and Rodriguez-Garavito, 2005; Evans, 2008; Rodriguez-Garavito, 2011). Law provides mechanisms and resources for the negotiation of public and private interests in the political arena – a political arena no longer contained within national states or political institutions in the narrow sense (Aman, 2004). Maximizing those opportunities will require yet new ways of thinking about law and its relationship to globalization.

Globalization: Welfare and Social Work

Abstract

Globalization is not a new phenomenon, but it has received relatively little attention in relation to welfare systems and social work. This article describes the understandings of this and related terms, with particular reference to economic globalization. It identifies some contemporary characteristics and trends and discusses how these affect welfare systems; and considers why and how globalization is relevant to social work and social development.

Introduction

The notion of 'globalization' entered public discourse in the 1990s and has since been the subject of much debate across a range of disciplines, as well as in the media. The characteristics – and risks and benefits – of this process have been elaborated and contested; and related terms have been articulated. Advocates have stressed the importance of economic globalization for human and societal development while social movements have developed to counteract the costs to particular communities or the whole planet.

Central features of globalization are international trade and the spread of people and knowledge across national and continental borders. The current phase of globalization is not unique, and antecedents can be found over two millennia or more but it was extended and deepened in the twentieth century by increasingly rapid and cheap transport and then advances in information and communications technology (ICT). Transnational corporations (TNCs) are the agents of globalization and, in addition to those already existing in Europe and the United States, new ones have been established in the BRIC countries (Brazil, Russia, India, and China) and other emerging market economies (EMEs).

Another essential feature of current globalization is the extent to which national governments have adopted neoliberal policies favorable to free market enterprise and global competition. Policies which favor reduction in the role of the state across a range of activities and which promote privatization or outsourcing of goods and services impact on domestic circumstances, including in relation to the extent and form of welfare systems. In the postfinancial crises (originated in the United States in 2008), many European governments have adopted austerity measures affecting large proportions of their populations, both those who have traditionally been the focus of social work concern and also those who were previously self-supporting.

Conversely, the relocation of jobs to low labor cost countries has brought employment to large numbers of people, e.g., in India and the EMEs, but has so far failed to benefit many economies in the global south, particularly those countries deemed to be fragile states. The espoused benefits of economic globalization have not been equally shared and there is evidence of an increasing gap between the 'haves' and 'have-nots,' with implications for welfare policies and provisions; for social development programs; and for social work in its varied forms.

This article explores current definitions of globalization and related terms. The major actors in (economic) globalization are identified and other aspects of globalization are considered. Some aspects of the relationship between globalization and 'welfare' are presented before examining some of the ways in which globalization has relevance for social work and social development. Alongside the international processes of globalization, various forms of regionalism have also been established in or between different continents: these are mainly economic arrangements (with a wider remit and influence in the case of the European Union) but only passing reference to regionalization can be made here.

Characteristics and Meanings of Globalization and Related Terms

Globalization has been examined from a variety of disciplinary perspectives, with different definitions being advanced for this and related terms. However, economic integration is usually taken to be the dominant form of globalization affecting other processes, including social and cultural. Das (2011: p. 18) states that while "… globality, globalism and globalization … are often narrowly defined in their economic meaning, they are broad in their meaning and implications." Economic globalization has a major impact on other processes and systems, although not all countries are integrated into the world system of interrelated economies and finance, and the form that globalization takes varies over time (Wallerstein, 1974).

The origins of 'global systems' can be traced to the post Second World War period when various institutions were established to promote world peace, economic reconstruction, and social development (e.g., the United Nations (UN) and its specialist agencies; the World Bank; and the International Monetary Fund (IMF)) (see Wilson, 2012; Baker and Hinds, 2012). However, in 1974 Wallerstein used the specific term, globalization, to describe "the expansion of capitalism to the point where a world economy was operational, thus creating a world system" (Lyons et al., 2006: p. 22). The term became widely used in public discourse and social science literature in the 1990s and writers in different disciplines recognized the extent to which various processes are interrelated and interact on each other. For example, Axford (1995: p. 5) linked economic and political processes evident in globalization to culture change. However, Khan and Dominelli (2000)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28036-7

described economic activity as the 'lynchpin' of globalization (p. 96) and identified the following key features:

- mobility of production processes from advanced capitalist countries to developing countries;
- the rising power and spread of TNCs worldwide;
- the liberalization of international finance systems; and
- reduction in transport and communication costs.

Das (2011: p. 18) describes "globalism" as "a network of connections spanning multi-continental distances, drawing them close together economically, socially, culturally and informationally." Globalization, in turn, is the process "promoting and intensifying multi-continental interconnectedness, and thereby increasing the degree of globalism" (Das, 2011: p. 18). As others have also observed, globalization overrides national boundaries and integrates societies and economies, leading to discussions about the role and power of the nation states (Held et al., 1999). As national power has apparently declined, due to both global and also regional processes (e.g., in Europe), the influence of TNCs has increased. They have played a major role in increasing the "international division of labor on the one hand and growing integration of national economies through trade in goods and services, cross-border corporate investment, and capital flows on the other" (Das, 2011: p. 18). While the power of individual states over national economies and the activities of TNCs and financial institutions has decreased, the role of the state has changed with an increase in powers related to regulation and surveillance. Such powers are evident in the field of migration and the limits placed on gaining citizenship in another country, as well as in relation to collective activities (e.g., trade unions) and the public sector. Such changes impact most on people who are least well off in specific societies and internationally, compounding the growing gap between corporate elites and others in national and global populations (Wichterich, 2000).

Alongside continuing questions about the power of nation states, the 1990s also saw expressions of concern about the possible decrease or even loss of national identity and culture, seeing globalization as responsible for an increasing homogenization of culture. For example, criticisms were voiced about the extent to which the rationalization of processes and the spread of uniform products of (what were then termed) 'multinational corporations' (MNCs, often US based) permeated countries in (economic) transition, struggling to (re)establish national identity and policies. Ritzer (1993: p. 99) suggested that the processes of globalization were leading to a situation where "people know what to expect at all times and in all places … (in) … a world that offers no surprises."

In the context of concerns in the 1990s about the social and cultural impact of globalization. The term, 'glocal,' was used to describe the relationship between the local and the global, with the concept of glocalization being developed by Bauman (1998). The terms have utility in a number of areas, including in indicating the transcultural relationships, which increasingly exist, not least in the personal/domestic arena through migration. While the terms themselves may not be in evidence, the balance of power between the global and the local has been further considered in this century. For instance, Gray and Fook (2004) "identified four sets of related tensions … globalization–localization; Westernization–indigenization; multi-culturalism–universalization; and universal–local standards" (cited in Healy, 2012: p. 13) and indigenization and globalization have been discussed together by Dominelli initially in 1997 as well as more recently (e.g., 2012).

As mentioned, the contemporary phase of globalization has been significantly enhanced by technological innovations, with ICT facilitating not only the operation of TNCs but also enabling an increase in information sharing and communication in a wider range of activities. These include not only an increase in international criminal activities (e.g., trade in arms, drugs, and people), but also the ability of migrants to retain connections with family and communities 'back home' and to forge transnational lifestyles (e.g., Negi and Furman, 2010). It has also underpinned the growth of critical responses to some of the consequences of globalization and the growth of global social movements (e.g., Dominelli, 2012) and the beginnings of a global civil society.

However, technological advances alone are not a sufficient condition for continuing globalization, which also requires the lowering and elimination of trade barriers; the deregulation of capital markets and domestic economies; the maintenance of balanced (national) budgets; and the opening up of banking and telecommunications sectors to private ownership and competition (Das, 2011). Many of these conditions were being met and advanced in the first decade of the twenty-first century although, in the aftermath of the economic crises in 2008, some are questioning the extent to which deregulation, for example, of financial institutions and capital markets, should be maintained. But it has two further conditions, privatization and the shrinking of government bureaucracies, which have had the most impact in countries where governments were heavily involved in welfare provision; and the changing economic conditions and political shifts have also had a bearing on social development initiatives in less-advanced economies (Midgley, 2012).

Globalization, Welfare, and Development

Measures to promote well-being and to support the development of various welfare measures require economic resources, but they also require particular policy directions and frameworks. A US social work academic described welfare as "the state of collective well-being of a society or community" (Van Wormer, 1997: p. 4). The term is variously used in conjunction with other words giving it more specific connotations. So, for instance, the term 'welfare state' suggests a range of provisions, including universal free education and health care as well as various income maintenance ('social security') measures and personal social/human services. Such systems were established in the second half of the twentieth century in the context of social democratic political systems then prevailing, e.g., in North West European and other countries (Gilbert, 2002). In other parts of the world, 'welfare' may have a different meaning, related to poverty relief (through state, voluntary, and private means) but income maintenance schemes are at very basic levels and/or limited in their reach (Midgley, 1997).

In addition, the lack of accountability of TNCs to national governments or international bodies allows free movement of capital and production to sites that benefit the corporations'

shareholders, with little regard for the social consequences in particular locations, notably, high levels of unemployment in areas/countries which firms have 'vacated' and, possibly, poor working conditions in developing countries (Akimoto and Sungkawan, 2012). The worst excesses of labor exploitation may be curtailed by international bodies (e.g., the International Labor Organization, ILO) or by public outcry, and some TNCs pride themselves on being good employers (e.g., providing 'decent work' and contributing to community resources), but problems related to unemployment and development of comprehensive welfare systems or even basic safety nets are not generally seen as the responsibility of commercial enterprises. However, transnational companies are increasingly involved in the provision of health and social care facilities, as well as the insurance schemes, which sometimes underpin access to these resources and pensions.

Teeple (2000) has argued that globalization marks the ascendency of economics over politics, of corporate demands over public policy, and of private interests over public ones; and that the rise of neoliberalism has undermined and reversed welfare state initiatives. New Zealand led the way in the 'dismantling of the welfare state' in the early 1990s although there had been anxieties about 'the crisis in welfare' in Europe and the United States from the 1980s (e.g., Pierson, 1996). By the twenty-first century, radical changes had taken place in many countries in the organization and provision of pension systems, health care, education, personal social services/human services, housing policies, and criminal justice systems. These systems all face further changes – downsizing of the public sector, outsourcing and increased emphasis on private sector provisions – in the light of 'austerity measures' being pursued by national governments in the wake of the 2008 economic crises (e.g., Hessle, 2012).

In some countries, moves to reduce the role of the state in welfare have been justified on the grounds that generous welfare provisions promote 'welfare dependency' and restrict choice and efficiency (Gilbert, 2002). Alongside efforts to reduce the welfare bill, countries have put considerable emphasis on employment as the main means of income and well-being for individuals and families, e.g., 'welfare to work' programs in the United States and social inclusion policies in the European Union (Lyons et al., 2006). However, the economic downturn and the shift to knowledge economies among postindustrial societies limit the extent to which jobs are available, particularly for less-skilled workers. Even the growth of the service sector (relative to manufacturing) offers diminishing opportunities for employment, for example, as high street retail stores go into liquidation in the face of competition from online purchasing.

These trends can be seen as an inevitable rebalancing of economies and employment opportunities at national and global levels, attributable to technological change and other global processes, but they have significant implications for the demands made on welfare and social development budgets, particularly as they occur in the context of demographic changes. Advances in health care and improved material benefits in the developed world have underpinned increased longevity and significant expansion in the proportion of older people (including frail elders) in many populations, including in Europe and North America. Conversely, improved health and education have reduced maternal and child mortality rates in the BRICs and emerging economies and also in some developing countries resulting in increased proportions of children and young people in their populations. The 'greying of the planet' places significant pressures on welfare provisions in the West, while a youthful population provides a ready supply of labor in many Asian and South American countries, but the lack of employment opportunities in many African countries has implications for development programs and affects migration patterns (e.g., Hokenstad and Roberts, 2012; Segal and Heck, 2012).

Cultural factors also affect the provision and take-up of such welfare provisions as exist or policies to increase welfare when up to 50% of national populations born female may be discriminated against, for example, in extreme cases being debarred from education or not having access to appropriate health services such as maternity care. The establishment of the UN's Millennium Goals has had some positive effects in increasing the take-up of education by girls in some countries and encouraging national governments to introduce policies and services which reduce maternal and child mortality rates, but it seems that in many places there has been little change in patriarchal societies where boy children are favored and girls are prevented from reaching their potential (Correll, 2008).

Finally, environmental factors, including climate change and extreme weather events, currently and potentially impact on the well-being of the worldwide population in one way or another (Alston and Besthorn, 2012). The concerted efforts of international bodies and national governments are needed to address these concerns, which also have implications for policy makers and practitioners in the welfare and development sectors. Such events have contributed to food insecurity (in the face of the expanding global population) exacerbated in some countries and regions by competition for water and fuel sources. In some cases, such competition contributes directly to interethnic and international conflicts. However, the latter also reflect significant economic inequalities and cultural differences, not least those related to religion, as exemplified in the Middle East (e.g., Al-Makhamreh and Libal, 2012).

Globalization, Social Work, and Social Development

References to globalization began to appear in the social work and social development literature from the 1990s. For example, in Europe, Trevillion (1997: pp. 7–8) suggested that social work was a product of the first wave of globalization (in this context, the late nineteenth/early twentieth century) and was now going through a transition to 'the new globalism of networks and markets,' while Midgley (1997) was writing about social development in the context of globalization. Globalization has been a theme addressed primarily in literature relating to international social work and Lyons (1999: p. 12) suggested that "internationalisation has been given an added impetus by the increased recognition of the relevance of globalisation to the welfare sector, and to the roles and tasks of social workers, whatever their arena."

'Social work' takes a range of forms nationally in the West, even in particular regions, e.g., Europe (Zavirsek and Lawrence, 2012), but is often restricted in its practices, relative to broader

understandings and practices in the social development field. Some writers have identified the need for a closer association between 'social work' and 'social development' as promoted, for instance by the UN and INGOs, in 'developing countries.' This would entail a more aware and integrated approach to the economic as well as the social aspects of human well-being and an appreciation that the flow of ideas and practices, generally from more-developed to less-developed countries, should be reversed so that 'western' social workers import and utilize some of the theories and practices common in the social development field. Midgley has long advocated this view and has suggested the term 'developmental social work' to describe the role of social investment in professional practice (Midgley and Conley, 2010). During the twenty-first century, the term 'international social work' has continued to be variously understood and the subject of a range of texts. Most recently, these include two handbooks (Healy and Link, 2012; Lyons et al., 2012), where globalization and its relationship to social work/development have been the focus of specific chapters as well as referred to elsewhere. Harris and Chou (2001: p. 161), acknowledging that the global economy would act as a major constraint on welfare development, utilized the term, 'glocalization,' for the processes whereby local policy and practices in relation to community care are impacted by global processes but mediated by national contexts and 'country specific institutional arrangements.' Dustin (2007), building on research in the community care field, illustrated the relationship between local and global trends when she drew on Ritzer's thesis to describe the commodification of care and effects of centralized managerial domination, evident in the growth of care management in the United Kingdom. Concerns have been expressed that the risks of educational colonization and professional imperialism are inherent in some forms of international social work and must be challenged (Payne and Askeland, 2008) while Dominelli has questioned whether there is such a thing, if social work is taken to be an inclusive entity in which each country has the right to specify its own modes of practice and traditions, even if borrowing from others (Dominelli, 2000).

A recognition of the influence and implications of globalization has been evident in the work of three major international professional organizations representing social work in its various forms, the International Association of Schools of Social Work (IASSW); the International Council on Social Welfare (ICSW); and the International Federation of Social Workers (IFSW). In 2000, general meetings of the IASSW and IFSW were held following a joint Congress, leading to an agreed international definition of social work (note, not international social work). Subsequently the two organizations collaborated in producing 'Global Standards for Social Work Education and Training' and 'Ethics in Social Work: statement of principles' accepted in 2004 (see IASSW or IFSW websites). These have raised questions about the universality of the assumptions, values, and practices on which these statements are based although it was not intended that they would be prescriptive or static (see, for example, Sewpaul and Jones, 2004).

Globalization has received increasing attention at international level in the social work/development fields, over the past two decades. For example, IFSW issued a policy statement on globalization in 1996 in response to a conference resolution expressing concern about the impact of neoliberal policies and structural adjustment programs. This document was revised and extended to include 'the Environment,' accepted by the membership in 2004. Most recently, the three international organizations – IASSW, ICSW, and IFSW, have collaborated to bring social work and social development into closer association at international level. In 2010, the ICSW issued three Briefing Papers (on The Impact of the Global Financial Crisis; Social Protection Floor Initiative; and Human Trafficking) and IFSW issued four Consultation Papers (including on Poverty Eradication and Aging and Older Adults) as part of a policy process aimed at establishing a Global Agenda, the main concerns of which were collectively agreed at a joint Conference in Hong Kong (2010) (see ICSW and IFSW websites). The revised version of the 'Global Agenda for Social Work and Social Development Commitment to Action' was presented to the joint social work and social development global conference in Sweden in 2012 (Global Agenda, 2012). The ICSW also issues a monthly 'Global Co-operation Newsletter,' updating readers on a variety of relevant developments (ICSW website).

Key and emerging themes in these documents and other literature have been increasing poverty levels and exclusion; migration; and environmental concerns. The first of these is discussed below as an example of issues with global dimensions, which are relevant to social and development workers.

Poverty and Social Exclusion

Concerns about poverty have been a central focus of social work since its inception (late nineteenth century) to address the negative impacts of industrialization and urbanization in Europe and North America. Similar processes have affected many other countries as they modernized during the twentieth century, while social development programs were established to address the needs of societies and communities lacking the infrastructure of industrial development. Poverty itself takes many forms and has been characterized as 'relative' in advanced industrial societies and absolute in the global south, where it can take extreme forms, when basic needs for survival cannot be met by individuals themselves (Desai and Solas, 2012).

Consequences of economic globalization have included the increase in the disparity in incomes between rich and poor people (both between different sectors of society within countries and between rich and poor nations) and the extent to which economic problems in one part of the world impact on populations elsewhere. It is ironic that, as the international community declared a Second United Nations Decade for the Eradication of Poverty (2008–2017), so the financial crises struck in Europe and the US, with ramifications for economies around the world. In both continents, previously self-supporting people lost their jobs and sometimes their homes and thus, new populations joined those groups traditionally identified as living in poverty and experiencing social exclusion. The latter term, deriving from French policy concerns (Lenoir, 1974), has been in evidence in both social work and social development literature from the 1990s. For example, it was introduced to European Union terminology from about 1990 and policies to promote 'social inclusion' are a core

feature of European regional policy as well as having spread (e.g., to Australia) (Lyons and Huegler, 2012).

Poverty and social exclusion reflect inequalities and power imbalances, evident in most societies: they are indicative of social injustices and violate the human rights of sections of the population. Local experiences and international perspectives have identified some people as being particularly vulnerable to chronic poverty or dramatic changes in national economic conditions and most likely to seek social work assistance. These include families where there is a lone parent or neither partner is in work; people with disabilities, or physical or mental health problems; older people; migrants, and children. Child poverty is a worldwide phenomenon, including in wealthy countries: it has been subject to various attempts to measure and address it over many decades but continues to be an enduring reflection of social inequalities (UNICEF, 2012).

Elder care is of particular concern to many western countries, as demand for residential and domiciliary services for older people increase, although physical infirmity may be less significant than various forms of dementia. The private sector has long played a major role in providing residential care homes for older people and increasingly, care home providers are transnational companies (Di Rosa et al., 2012). A growing trend is the recruitment of 'overseas workers' to staff such homes, either because of shortage of local labor or to reduce labor costs. For example, in Europe, staff are recruited from neighboring countries or further afield, with implications for both the residents and the workers themselves (e.g., Di Rosa et al., 2012). In addition, in the case of Europe, over the last two or three decades, a proportion of (healthy) older people from North European countries had sought cheaper living conditions in warmer climes, e.g., Spain, but recently anecdotal evidence suggests that they have had difficulties selling properties and face problems paying for the accommodation or care they need if returning to their country of origin. Most extremely, it has been reported that, while some older German people are living in care homes in Hungary, Greece, and even Thailand by choice, others are apparently being 'sent' to rehabilitation centers or long-term retirement homes outside Germany, e.g., in Slovakia. The reasons given are primarily economic (the rising costs of care homes relative to the level of pensions), but it is also suggested that older people's increased needs are met by a better standard of care abroad (Connolly, 2012: p. 21).

Concluding Comments

Globalization has been evident in various forms over many centuries, increasing in its reach and the extent to which markets and other aspects of human life are integrated to the current state of globalism. The economic aspects of globalization predominate over other aspects (including social and cultural) although these have been increasingly 'facilitated' by political processes and international agencies. Major changes are currently taking place in the balance of power between 'western' and 'eastern' economies. However, even before the twenty-first century financial crises in the United States and Europe, governments in many countries were keen to curb public expenditure and the role of the state in welfare in line with political ideology. Many governments have since adopted austerity measures affecting both those sectors of the population who have traditionally relied on welfare benefits and social work interventions and also new groups affected by the shifts in employment opportunities (from west to east) and the impact of ICT.

In addition to the increase in rapid and relatively cheap transport, the revolution in digital technology has played a significant role in the expansion of TNCs but has also been utilized in other sectors, ranging from the spread of international criminal organizations to the maintenance of transnational family networks. ICT has also facilitated the establishment of social movements (including some in opposition to capitalism) and plays a significant role in the spread of information and international conventions (promoted by bodies associated with the UN) and in the exchange of ideas and practices in welfare and professional fields.

An awareness of the impact and implications of globalization on welfare, social, and development work has been in evidence since the 1990s and further attention has been given to the topic in the context of increased literature about international social work (broadly conceived). Global demographic trends and migration have particular implications for varied forms of social work organization and practices, worldwide, while social development initiatives in less economically developed countries have also been impacted. Three international bodies representing social service organizations and professionals are increasingly engaging with globalization (not least as its processes affect the distribution of resources within and between nations) and with international bodies, which seek to address some of the trends and issues associated with globalism.

Goal-Oriented Behaviour Among Human and Non-Human Primates

Heidi L Marsh, University of Western Ontario, London, ON, Canada

Abstract

We review the literature surrounding the phylogenetic and developmental emergence of goal-oriented behavior, among human and nonhuman primates. We define goal-oriented awareness as the ability to perceive goals and perceptions in others. We examine empirical literature involving gaze-following, shared attention, distinguishing between actions and intentions, and the ability to generate and understand communicative cues. We conclude that at least a rudimentary awareness of goal-oriented behavior is present from birth in humans, and in adult great apes. The evidence in other primate species shows phylogenetic differences as well as gaps in the empirical literature.

Social cognition includes any process that enables conspecifics to interact together effectively, including verbal and nonverbal signals. Although sociality in human adults is largely comprised of the former, the latter are informative because they exist in both preverbal children and nonhuman primates (hereafter, primates), and thus, represent the development of social cognition in its earliest forms. In this article, we examine one aspect of nonverbal social cognition – goal-oriented behavior – as it develops both ontogenetically and phylogenetically. We discuss the theoretical and methodological challenges inherent in the study of this behavior. Next, we trace its development in infants and primates, as seen in the ability to follow gazes and share attention, infer goals and distinguish intentions, and understand and use communicative cues. We conclude that both populations exhibit goal-oriented behavior, and further, that the evidence of such abilities so early in life (in the case of humans), and phylogenetically (in the case of primates) suggests a critical predisposition for more complex social abilities.

Defining Goal-Directed Behavior and Intentions

Predicting a social partner's goals is a critical, yet complex aspect of social cognition. Humans and other animals are similar to nonliving moving objects, in that they have physical characteristics (e.g., form, color, and size), but they are different in that living beings have inner lives that drive their behavior: They communicate, and have feelings and intentions, in ways that are often outwardly subtle (Gelman and Spelke, 1981). Moreover, unlike inanimate objects, social animals react to the physical and social environments in which they are embedded. This makes the behavior of social partners much less predictable than that of nonliving objects.

Because primates (human and nonhuman) have complex social lives, maintaining relationships demands flexible socio-cognitive abilities. Human adults are experts at predicting others' behavior because they react to overt behavioral cues, and they know that people act according to mental processes that allow them to plan and choose between different actions to attain goals. Without an understanding that behavior is organized by a governing sense of purpose, it would be nearly impossible to form accurate predictions or interpretations of others' behavior. Understanding goal-oriented behavior, therefore, requires the ability to both perceive what another is doing, and why (i.e., what is the desired outcome?) This would allow an individual to predict a social partner's behavior, even if the desired end state is not achieved. Moreover, as noted by Call and Tomasello (2008: p. 189), in order to perceive a social partner as goal-directed, an individual "must understand not only his goals but also his perceptions because what he sees and knows helps to determine what he does." Thus, an individual who has an understanding of goal-directed action should follow gazes and understand some connection between seeing and knowing; distinguish between action sequences that have the same external appearance, but which differ by the underlying intention; and read and use communicative gestures effectively.

Note that this constellation of abilities might not result in a comprehensive appreciation of the psychological states of others (i.e., a representational theory of mind, or ToM), as we know exists in human adults. For instance, the definition above does not imply an awareness of another's beliefs (which may differ from the true state of the world). The current literature suggests that neither infants nor primates have a representational ToM, in which they are aware not only of others' minds, but also that their thoughts and beliefs might differ from their own (Sabbagh et al., 2013; Call and Tomasello, 2008). Therefore, an understanding of goal-oriented behavior in others might be viewed as a rudimentary, but essential and precursory component of a representational ToM.

Theoretical Orientations

Although it is generally agreed that goal-oriented behavior plays a significant role in social cognition, several aspects of this ability remain under debate. Among developmentalists, there are differing views on the time line of its emergence. Most agree that by 4 years of age, children are aware of the minds and beliefs of others and further, those thoughts and beliefs may differ from their own (Wellman, 1990). However, preverbal children's understanding of others' minds remains a controversial subject. One viewpoint is that infants are born as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23075-4

a 'blank slate,' and can only learn to socialize through experience (James, 1890; Piaget, 1954). Accordingly, infants must learn to distinguish between physical and underlying psychological states through a domain-general process. Thus, for the first 2 years of life, infants perceive social partners only in terms of their external physical behavior, rather than psychologically, and do not become aware of the thoughts underlying actions until as late as the end of the second year of life (Piaget, 1954).

In contrast, others assert that infants are born with a 'social brain,' containing domain-specific abilities that make newborns preadapted to social interaction (e.g., Grossmann and Johnson, 2007; Trevarthen, 1979). This allows them to process information about the social environment differently from the physical world (e.g., Grossmann and Johnson, 2007). According to this view, the mind consists of specialized domains that each process represents certain kinds of information (e.g., Legerstee, 2013). The social cognition domain directs infants to perceive social input appropriately. Within this framework, it is possible to examine rudimentary nonverbal social abilities during the first 2 years of life to trace the development of social cognition. It is from this latter perspective that we examine goal-oriented behavior in infants and toddlers. Because normal sociocognitive development is dependent not only on biological predispositions, but also on interactions with the social environment, it should be noted that there are cultural variations in the development of goal-oriented behavior, particularly with respect to the time line of the emergence of the abilities described below.

In comparative psychology, the problem is somewhat different; while we know that human children will eventually develop a representational ToM because this ability exists in adults, the same cannot be said with certainty about primates. Among comparative researchers, theoretical controversies focus on *whether* primates have goal-directed awareness, rather than *when* it emerges. In their seminal paper, Premack and Woodruff (1978) assessed whether a chimpanzee understood the goals of a human who was confronted with a series of physical problems, and tentatively claimed that chimpanzees showed evidence of a ToM. However, 20 years later, evidence seemed to suggest the opposite (see Tomasello and Call, 1997; for a review). Many argued that Premack and Woodruff's (1978) results could be explained in terms of 'lower-level' mechanisms such as learned associations between stimuli (e.g., Savage-Rumbaugh and Rumbaugh, 1979). Subsequent studies also failed to find evidence in support of complex social cognition, such as understanding others' goals, perceptions, or false beliefs, in apes (e.g., Call and Tomasello, 1999; Povinelli et al., 1994). This led many to conclude that primates did not perceive others as psychological beings, after all (e.g., Heyes, 1998; Tomasello and Call, 1997).

More recent evidence suggests the contrary. Although most agree that a representational ToM has not been established in primates (Call and Tomasello, 2008; Penn and Povinelli, 2007), much of the accumulating evidence suggests that primates can read below surface behavior to gain insights about the goals, perceptions, and knowledge of others (cf Call and Jensen, 2007; Rosati et al., 2010; Tomasello et al., 2003). These theorists argue that even if a 'lower-level' interpretation could explain a single empirical result, several such explanations would be required to account for the vast convergence of evidence favoring the mentalist explanation (Call and Tomasello, 2008). At present, it is more parsimonious to hypothesize a single unifying explanation: apes (and perhaps some monkeys) have knowledge about the goals and perceptions of others. It is from this perspective that we review the comparative literature examining primates' goal-oriented behavior.

Methodological Considerations

Infants, toddlers, and primates all lack the ability to verbalize their knowledge. As a result, developmental and comparative researchers are forced to rely on behavioral and/or biological measures to evaluate subjective understanding. This is particularly difficult when the question of interest is whether subjects have an awareness (which is not directly observable) about the internal states (goals, perceptions, and knowledge, which are also not directly observable) of others. Researchers have devised increasingly clever methods to gauge this understanding, but several issues remain.

One method that is often used in developmental psychology is visual habituation. This method assesses whether infants look differentially at actors that behave intentionally versus those that do not, suggesting that they appreciate the goal directedness of their actions (e.g., Trevarthen, 1979). However, it is difficult to prove conclusively that these attention biases reflect a comprehension of the underlying intentionality, rather than a superficial discrimination between external patterns of behavior. This issue has been addressed by using control conditions, in which external patterns of behavior are matched between intentional versus accidental situations, so that discriminative looking must be based on the underlying motives (e.g., Woodward, 1998). However, even these conditions are problematic, as infants might focus solely on the outcome, and thus perceive people's actions as no more than bodily movements. One solution is to adopt paradigms that involve unsuccessful or invisible outcomes, because they separate the visible end point from the underlying goal (e.g., Brandone and Wellman, 2009; Hamlin et al., 2008).

Other studies test whether infants can imitate incomplete actions, because this avoids some limitations of visual attention paradigms, such as reactions to novelty effects. If infants can complete an unseen goal, this suggests that they inferred the underlying motive, even though it was never physically demonstrated. However, requiring an infant to imitate an action sequence is physically demanding, particularly with younger infants. Alternatively, researchers can compare infants' communicative behaviors (e.g., reaching and banging arms) between situations in which a social partner's intentions differ (e.g., Behne et al., 2005). In these studies, the social partner's body movements are matched between conditions, as is the outcome of the interaction (e.g., a toy is not shared), so differential responses between conditions appears to result from an understanding of the underlying intention.

A final issue in developmental psychology is that studies occasionally use similar methods but find different patterns of results, with infants of comparable ages (cf Behne et al., 2005; Marsh et al., 2010). This highlights the need to select age-appropriate behavioral measures. For instance, it is possible

that infants at different ages use different responses, such as conventional (e.g., affective responses and instrumental reaches) at younger ages versus more stylized communicative responses at older ages (Crais et al., 2004; Mosier and Rogoff, 1994).

Like research with infants, comparative studies on social cognition in primates demonstrate the importance of methodology. Researchers testing the same or closely related species have found conflicting results depending on their methodology (Barth et al., 2005). Sometimes, the methodological detail responsible for the resultant difference can be ascertained; for instance, consistent differences have been found in social cognitive tasks that are competitive versus cooperative in nature (Hare and Tomasello, 2004). Unfortunately, it is not always obvious what caused the difference in results, because discrepancies between the reported methods are not apparent. Additionally, many experiments require primates to infer the goals of a human, rather than a conspecific. It is possible that their performance on these tasks might be facilitated if primates were given more naturalistic social contexts, in which to infer goals (cf Hare and Tomasello, 2004; Itakura et al., 1999). This underscores the importance of choosing methodological details with care, bearing in mind the natural ecology of the species under investigation.

Finally, an issue in many primate studies is the limited availability of captive primates. Indeed, much of what is known is based on only a few species – capuchins, rhesus monkeys, and chimpanzees – due to their prevalence in research facilities and zoos. Although this has resulted in a rather comprehensive body of knowledge on these species, it has come at the expense of learning about phylogenetic trends. Additionally, limited sample sizes mean that only a narrow range of ages are represented. Many studies include only adult subjects, and those including juveniles often have only a few, leading to a poor understanding of the developmental trajectories of socio-cognitive abilities in primates (chimpanzees are an exception – see Matsuzawa et al., 2006; Tomasello and Carpenter, 2005; Tomonaga et al., 2004). Often, trends emerge that suggest there may be developmental or sex differences, but firm conclusions cannot be drawn due to the limited sample size.

Development of Goal-Directed Behavior

Goal-Oriented Visual Behavior

From birth, human infants are attracted to agents that act intentionally (Trevarthen, 1979). They attend to faces, eyes, voices, and body movements (e.g., Markova and Legerstee, 2006). By 2–3 months of age, if a social partner suddenly halts a conversation with an infant, the infant shows a characteristic response to the adult's sudden 'still face' (Tronick, 1978): They reduce smiling and gazing, while trying to reengage the partner. Some theorists posit that these reactions reveal infants' understanding that when people look at them, they intend to communicate (e.g., Tronick, 1978).

Studies using visual habituation have also demonstrated that infants appreciate the goal directedness of successful actions during their first year (e.g., Woodward, 1998). Six-month-old infants respond to human actions, but not nonhuman ones, as though they are goal directed (e.g., Woodward, 1998). In an 'unsuccessful action' study (in which an internal goal is attempted, but not achieved), using visual habituation, 10- and 12-month-olds inferred the goal directedness of both successful and unsuccessful reaching actions, but 8-month-olds only recognized the goal directedness of successful actions (Brandone and Wellman, 2009). Other research using visual habituation suggests that the ability to infer unfulfilled goals might emerge even earlier, in 6-month-olds (e.g., Legerstee et al., 2000).

Between 5 and 7 months, infants also look to faces as a source of information during ambiguous situations. In a study, 7-month-old infants looked at an adult's face (as if to say, "Why are you doing that?") significantly more often when the adult teased the infant, by preventing a ball from being shared, than when the ball was given in the expected manner (Legerstee, 2005: ch. 5). It has been argued that this type of gaze-monitoring indicates mental state awareness, because typically developing infants, but not infants with autism, monitor the gazes of people more often in ambiguous situations than in nonambiguous situations (Phillips et al., 1992).

Visual behavior during triadic social interactions (a social dyad plus a third individual or object) is another indicator of infants' goal-oriented awareness. Gaze-following implies that infants are aware that their partner sees/perceives the same object that they do (coordinated attention), their speech concerns that object (labeling), and/or the emotion on the person's face is a result of looking at the object. These behaviors develop in increasing complexity during the first year of life (Legerstee and Barillas, 2003).

Infant gaze-following has also been tested using 'object-choice' tasks, in which a prize is hidden in one of several objects, and an adult indicates its location by gazing at it. The rationale is that if an infant chooses the correct object, based on the direction of the gaze, then the individual understands the communicative intent behind the behavior. Several studies have shown that infants as young as 18 months can do this successfully and appear to do so spontaneously (e.g., Itakura and Tanaka, 1998; Tomasello et al., 2007).

The visual behavior of some primates shows a striking resemblance to humans. For instance, mutual gaze as a means of communicating social intent is also seen between mother and infant chimpanzees. Matsuzawa (2006) has argued that this behavior – unique to hominoid species (humans and apes) – may be a precursor for the human mother–infant relationship. Mutual gaze is generally not present among monkey species, for which direct gaze is often perceived as a threatening signal. This behavior increases at 2 months of age, which coincides with the onset of social smiling in this species (Bard et al., 2005). Further, like humans, infant chimpanzees show a visual preference for stimuli that mimic goal-directed behavior versus those that do not (Uller, 2004).

Object-choice tasks have also been used to test primates' abilities to follow gazes. However, primate eyes differ morphologically from human eyes: The sclera in most primate species is not white, as it is in humans, and less of the sclera is visible, making it much more difficult to detect the direction of gaze. Consequently eye gaze is not as salient as a social cue in primates (Kobayashi and Kohshima, 2001), and great apes have been shown to rely more on the orientation of a head than gaze direction to locate a hidden object (Tomasello et al.,

2007). Thus, many studies examining this ability include not only gaze-orientation conditions, but also head orientation (e.g., Itakura, 1996; Marsh, 2012; Tomasello et al., 2007). The balance of research suggests that apes can use gaze or head orientation as a cue, and appear to do so spontaneously, or with minimal training (e.g., Call et al., 1998; Marsh, 2012; but see Barth et al., 2005; Itakura et al., 1999). The ability to follow gazes emerges in infant chimpanzees around 9 months of age (Okamoto-Barth and Tomonaga, 2006), although other research suggests it may occur later in ontogeny (Tomasello et al., 2001). This behavior has been cited as evidence that apes, like infants, understand the communicative intentions underlying visual gestures.

Research with monkeys and prosimians (which are more distantly related to humans than apes) provides less evidence to support spontaneous use of gaze. Although many species of monkeys follow gaze and/or coorient (e.g., Ruiz et al., 2009; Tomasello et al., 1998), they seldom use this social cue as a source of information in object-choice tasks, at least without extensive training (e.g., Anderson et al., 1995, 1996; Itakura, 1996). Thus, there may be a phylogenetic divide between hominoids and monkeys in terms of understanding the communicative significance of gaze and head orientation as an intentional social cue.

Another similarity between apes and infants is that apes also have a tendency to check back to a social partner's face (social referencing) when faced with uncertainty. For instance, if they follow a social partner's gaze, but fail to see any obvious target, they will check back to the social partner to ensure that they have followed the gaze correctly (Bräuer et al., 2005; Call et al., 1998). This suggests that they have expectations about the reasons underlying a social partner's gaze, and expect to see something interesting at the same location. In this case, however, it appears that the function of the apes' behavior may be to confirm the direction of the social partner's gaze (i.e., what are you looking at?), rather than checking intentions (i.e., why are you looking at that?). This behavior has not been observed in monkeys.

Finally, several experiments have investigated whether primates understand the connection between seeing and knowing. Although this remains a controversial topic, some research suggests that apes understand something about the perceptions of others, whereas monkeys do not. Specifically, apes adjust their rates and locations of gesturing to experimenters and/or conspecifics, depending on the attentional state and direction of the experimenter (e.g., Kaminski et al., 2004; Povinelli et al., 2003). They can also adopt the perspective of conspecifics, and adjust their behavior accordingly (Hare et al., 2000). In contrast, although some monkey species can follow gazes, it has been argued that this behavior is reflexive in nature and does not demonstrate an understanding about what others see (Rosati et al., 2010). This may again represent emerging complexity in social cognition, across phylogenetic time.

Goal-Oriented Behavioral Responses

From 9 months of age, infants imitate novel and combined action sequences (Meltzoff, 1988). When shown a human agent, a nonhuman agent (stuffed animal), and a surrogate object with mechanical pincers as hands, 10-month-old infants reenacted the successful actions of the human and nonhuman actors, but completed the goals of the human agents only (Legerstee and Markova, 2008). These findings were replicated with 7-month-old infants in a simplified imitation task (Hamlin et al., 2008). Further, 14- and 18-month-old infants imitate intentional action sequences, but not behavior that appears to be accidental (Carpenter et al., 1998).

Rather than relying on imitation, Behne et al. (2005) measured infants' natural behavioral responses (e.g., reaching and banging their arms) to a series of situations. They found that 9-, 12-, and 18-month-olds, but not 6-month-olds, reacted differently when an adult was unwilling rather than unable to pass a toy, despite perceptually matched, similar outcomes (the toy was not shared). Using a similar method but different behavioral measures, such as smiles and vocalizations, Marsh et al. (2010) demonstrated this ability in 6-month-olds.

This paradigm has also been used with primates. Both chimpanzees (Call et al., 2004) and capuchin monkeys (Phillips et al., 2009) stayed longer in a testing area and showed less frustration when an experimenter was trying, but unable, to give food than when she had no intentions of sharing. Moreover, capuchins showed this behavior with a human social partner, but not when analogous but inanimate objects were used (Phillips et al., 2009). In similar studies, in which the superficial movements of an experimenter were matched between conditions, but the context of the behavior suggested different intentions, apes once again demonstrated the ability to infer underlying goals (Warneken and Tomasello, 2006; Buttelmann et al., 2012). Other research shows that both monkey and ape species can discriminate between accidental and goal-directed behaviors in others (Call and Tomasello, 1998; Lyons and Santos, unpublished data). For instance, in object-choice tasks, apes choose objects that have been intentionally marked by an experimenter, rather than those that were inadvertently marked (Call and Tomasello, 1998).

Comparative researchers have also investigated primates' imitation of goal-directed actions. Like young children, apes are more likely to imitate goal-directed actions (e.g., Call et al., 2005), even when they are unsuccessfully demonstrated (Tomasello and Carpenter, 2005). Moreover, they can infer and complete goals using alternate means, rather than imitating goal-irrelevant behaviors (i.e., goal emulation; Buttelmann et al., 2007; Horner and Whiten, 2005). Whether this ability is shared more widely among primates is, as yet, unknown, as there has been little research conducted beyond hominoid species.

Use of Goal-Oriented Communicative Cues

Before infants use speech to communicate, they use gestures such as pointing, giving, and requesting to direct people's attention to aspects of their environment (Bates et al., 1975). Imperative pointing is a goal-oriented instrumental behavior to direct another's actions (e.g., "I want that thing"). In contrast, declarative pointing, when an indicated object or event is used as a means of making a nonverbal comment (e.g., "Wow, look at that!"), reflects recognition that one can share experiences and information with others and has been linked to the emergence of an understanding of intentions (Camaioni et al., 2004; Legerstee and Barillas, 2003). Current evidence suggests that imperative pointing emerges first, ontogenetically, but

declarative pointing is evident by the end of the first year of life (Camaioni et al., 2004; Liszkowski et al., 2006).

Infants' understanding of communicative gestures has been examined using object-choice tasks. Children as young as 1.5–2.5 years of age can use a social partner's pointed finger to locate a hidden prize, and do so spontaneously (e.g., Itakura and Tanaka, 1998; Povinelli et al., 1997). This suggests that they understand the communicative intention underlying the gesture, especially given that their performance with pointing cues is superior to that with inanimate markers (Tomasello et al., 1997). Sodian and Thoermer (2004) used a visual habituation paradigm to demonstrate that even 1-year-old infants understood the goal underlying a social partner's reaching gesture. They noted, however, that although infants followed a social partner's point, they did not yet understand the referential intent or goal underlying it.

In apes, there is also evidence from object-choice tasks that individuals can spontaneously use an experimenter's pointed finger as a cue (e.g., Itakura and Tanaka, 1998; Marsh, 2012), although contradictory results have been found (e.g., Povinelli et al., 1997; Tomasello et al., 1997). Moreover, one ape species (orangutans) learned to use socially given cues significantly faster than inanimate markers that were matched for spatial location (Marsh, 2012). This suggests that the social component (and perhaps the communicative intentions underlying the gestures) facilitated their understanding.

Monkeys have more difficulty in using communicative cues, such as pointing or reaching (e.g., Anderson et al., 1996), at least without extensive training (e.g., Anderson et al., 1995), suggesting that they do not understand these types of cues spontaneously (but see Hauser et al., 2007). Therefore, this is another aspect of goal-oriented understanding that may have emerged more recently, phylogenetically. Moreover, evidence for the *production* of spontaneous gestural communicative cues is also much stronger in ape species, than in monkeys (e.g., Blaschke and Ettlinger, 1987; Tanner and Byrne, 1999). However, whether or not apes grasp the intentional meanings behind their communicative gestures remains under debate (e.g., Call, 2010; Cartmill and Byrne, 2010).

Conclusion

Based on the evidence reviewed, it is clear that at least a rudimentary awareness of goal-oriented behavior is present from very early on developmentally, in humans, and phylogenetically, in primates. In particular, there are striking resemblances between human infants and great apes (chimpanzees, bonobos, gorillas, and orangutans), whereas the evidence in non-hominoid species (such as monkeys and/or prosimians) shows both demonstrated differences as well as empirical gaps in the literature.

With respect to goal-oriented visual behavior, newborn infants and infant chimpanzees show visual preferences for agents that display goal-directed behavior. By 2–3 months, human and chimpanzee infants engage in mutual gaze and increased social smiling, as a means of communicating social intent in mother–infant dyads. Older infants (5–7 months) and great apes also check back at faces of social partners, as a form of social referencing, although the reasons they do so may differ between species. Monkeys, to date, have not been recorded engaging in this behavior.

From 5 to 15 months, infants show increasing complexity in gaze-following and joint attention. They also follow others' gazes as a cue during object-choice tasks, and do so spontaneously, from as young as 18 months. Apes also show the ability to follow an experimenter's gaze in an analogous task and can use gaze (usually in conjunction with head orientation) to solve object-choice tasks spontaneously, although contrary evidence exists. To date, prosimians and monkeys appear to have much more difficulty in using gaze as an informative social cue, particularly without extensive training.

There is also strong evidence for the ability to distinguish intentions based on unsuccessful actions in both infants and primates. Infants have demonstrated this ability between 6 and 12 months, both through their visual behavior, as well as in their imitative and communicative behaviors. Great apes and capuchin monkeys can also infer underlying goals and/or distinguish between an experimenter's intentions, despite similar external patterns of behavior. Primates can also discriminate between accidental and goal-directed behaviors. Thus, this is one area in which monkey species show convergent patterns of behavior with apes and human infants. However, only apes and infants have, thus far, shown the ability to imitate goal-directed actions and engage in goal emulation.

Finally, human infants, from approximately 12 months of age, and at least some great apes, engage in communicative gesturing. Although infants appear to do so intentionally and referentially, it remains unclear whether this is the case for apes, and whether gesturing occurs spontaneously at all in monkeys. Human infants (from approximately 1.5–2 years of age) and apes also use a social partner's reach or point as a cue to locate prizes in object-choice tasks, and do so more effectively than with inanimate cues that are matched for spatial position. Monkeys have much more difficulty in using these types of cues, particularly without extensive training and experience.

Taken together, humans, across the first 2 years of life, and at least the great ape species, show abilities consistent with an understanding of goal-oriented behavior, across several behavioral categories. Given that the extant great ape species began to diverge from the human lineage some 10 million years ago, it is possible that this increasing sociocognitive complexity was, and continues to be, a necessary and precursory component of the multifaceted mental awareness that we see in modern day human adults.

Abstract

Erving Goffman (1922–1982) is considered to be one of the most important sociologists of the latter half of the twentieth century. He began his academic career at the University of Toronto and completed his sociology studies at the University of Chicago, where he primarily studied under Everett C. Hughes and W. Lloyd Warner. From 1962 Goffman was a Full Professor at Berkeley. In 1968 he accepted the Benjamin Franklin Professorship at the University of Pennsylvania in Philadelphia, where he wrote his *chef d'oeuvre 'Frame Analysis'* (1974). Goffman's main theme was the forms of immediate social interaction, 'face-to-face' encounters. He saw in them a specific type of social system and a sociological field in its own right. Goffman focused on tiny moments of people's behavior, which they themselves find more or less natural and are unaware of: fleeting glances, physical contact, apologies, greetings, compliments, silence, etc. All of Goffman's works, 11 books in total, are consistently oriented towards this empirical reality, but from the start Goffman also coined or redefined concepts and models (dramaturgy, role, identity, stigma, ritual, total institution, strategic interaction, frame, etc.). Goffman left behind a series of studies that are still relevant and influential today, and a network of concepts that is both highly complex and highly integrated.

The work of the sociologist Erving Goffman is regarded as a classic by most of his professional colleagues. Randall Collins (1988, p. 41) even considers him 'the greatest sociologist of the latter half of the twentieth century.' Goffman's influence, particularly on many younger researchers, is still powerful at the beginning of the twenty-first century and is by no means restricted to sociology. Goffman's works have been influential in numerous parallel disciplines, above all in social psychology, linguistics, philosophy, literature studies, pedagogics, psychiatry, and media studies. It cannot be denied that Goffman made important empirical, theoretical, and methodological contributions. The following essay will discuss them against the background of a short biographical sketch and relate them to relevant sociological contexts of discussions.

Biographical Sketch

Erving Goffman was born in the small Canadian town of Manville on 11 July, 1922, the son of Russian-Jewish immigrants. He began his academic career at the University of Toronto, where he took his BA in 1945. After completing his sociology studies at the University of Chicago, USA, where he primarily studied under Everett C. Hughes and W. Lloyd Warner, he took up his first post in Scotland, UK. From 1949 to 1951 he worked at the Department of Social Anthropology at Edinburgh University. After that he returned to Chicago, where he gained his doctorate with his thesis *Communication Conduct in an Island Community*, which he had prepared in Scotland. The empirical basis of his dissertation, which was supervised by W. Lloyd Warner, Donald Horton and Anselm L. Strauss, was a field study on the Shetland Islands. Following a spell as research assistant at the Department of Sociology at Chicago University, where his research included social stratification, Goffman was employed as a Visiting Scientist in the Laboratory of Socio-Environmental Studies at the National Institute of Mental Health (NIMH) in Bethesda (Maryland) from mid-1954 to the end of 1957. During this time Goffman carried out a one-year study in a mental hospital. This study on the basis of 'participant observation' formed the essential foundation of his book *Asylums* (1961a). In 1958 Goffman transferred to Berkeley as Assistant Professor of Sociology and member of the Center for the Integration of Social Science Theory at the University of California. From 1962 he was a Full Professor in Berkeley. In 1968 he accepted the Benjamin Franklin Professorship at the University of Pennsylvania in Philadelphia, where he substantially advanced his research program and wrote his *chef d'oeuvre 'Frame Analysis'* (1974).

His works, which reached a wide academic and non-academic audience and have been translated into many languages, earned Goffman numerous honors. He received a number of prestigious awards and was Visiting Professor at several universities at home and abroad. In 1981 Goffman became President of the American Sociological Association (ASA). At the peak of his powers after an academic career of almost 30 years, Goffman died on 20 November 1982.

Goffman's Work

Research Program and Intellectual Context

Goffman's main theme was the forms of immediate social interaction, 'face-to-face' encounters. He saw in them a specific type of social system and a sociological field in its own right. In his Presidential Address delivered at the end of his term as President of the American Sociological Association shortly before his death, he declared: 'My concern over the years has been to promote acceptance of this face-to-face domain as an analytically viable one – a domain which might be titled for want of any happy name, the interaction order – a domain whose preferred method of study is microanalysis' (Goffman, 1983, p. 2). This programmatic description of his position does not mean that Goffman regarded the interaction level as completely autonomous or socially fundamental. Rather he

stressed the manifold 'relativity' of the autonomy of the interaction order. In many places in his works Goffman pointed out its historical variability as well as links ('a loose coupling') between the micro-level of the interaction and social macro-structures (e.g., social stratification or bureaucratic organization). However, Goffman did not systematically consider the historical and social conditions and dependencies of his subject. Rather he was primarily concerned with observing and discovering seemingly insignificant aspects of daily behavior. He focused on tiny moments of people's behavior, which they themselves find more or less natural and are unaware of: fleeting glances, physical contact and distance, apologies, greetings, compliments, silence, etc.

All Goffman's works, 11 books in total, are consistently oriented towards this empirical reality, but from the start Goffman also adopted means of interpretation from various sociological schools and traditions, including above all the 'classics' William James (*see* James, William (1842–1910)), Emile Durkheim (*see* Durkheim, Émile (1858–1917)) and Georg Simmel (*see* Simmel, Georg (1858–1918)), structural functionalism (Alfred Radcliffe-Brown, Talcott Parsons (*see* Mead, George Herbert (1863–1931))), representatives of the Chicago School (George H. Mead (*see* Mead, George Herbert (1863–1931)), Charles H. Cooley, Louis Wirth et al.), existentialism (Jean-Paul Sartre), ethology, ethnomethodology (Harold Garfinkel, Harvey Sacks), and sociolinguistics (Dell Hymes). But Goffman never regarded his theoretical references, models and metaphors as ends in themselves, they were rather means to the end of discovering and describing social order.

Approaches, Positions, and Results

In the following attempt to briefly summarize and appraise Goffman's work, a number of key sociological terms either coined or redefined by Goffman will be used as a guideline.

Dramaturgy

Goffman became known for his analysis of social life based on the model of the theater (see 1959), and his model has remained influential. It is too simple to speak of Goffman's work, as for example Jonathan Turner does, as the 'dramaturgical school of interactionism,' but it can be demonstrated that the dramaturgical perspective consistently played an important role for Goffman. It can similarly be proved that Goffman's dramaturgical approach partly anticipated and formed a basis for many of his later constructs. This particularly applies to his works on strategic interaction, ritual, territoriality, identity, and stigma.

Within the context of the theater model Goffman reconstructed above all the strategies of social 'face work': forms of concealment, lying, self-stylizing, mystification, the manipulation of 'facades,' etc. His aim here was not just to show how individuals, selfish subjects in the fight for social recognition, attempt to present themselves in the best light; rather he constantly also saw dramaturgical everyday life as producing and reproducing social order, a restrictedly open and widely endangered process that is to be permanently established.

Goffman's dramaturgical approach and his later reflections on social territories (1971) and frames (1974) also help us understand the spatial organization (social ecology) of modern society. For example, it becomes clear that normality is a fictional impression to be produced by differentiating distinct spheres of perception, audiences, and representations; it is the foundation for the actors' basic social trust. Goffman's differentiation between 'frontstage' and 'backstage' (see 1959) became famous in this context.

Roles and identities

Goffman's early works in particular are to be seen in the context of role theory, influential at the time, which he criticized and developed further. Goffman treated role analysis primarily as interaction analysis, investigating the functioning and organization of the 'actual' practice of performing a role against the background of its normative frame. Thus Goffman developed concepts of patterns and styles of behavior, including the term 'role distance' (see 1961b), which has meanwhile acquired the status of a basic sociological term and which refers to a way of behavior which comments on the role and primarily serves either the interaction system or the selves relevant in the situation. For example, Goffman described a five-year-old boy riding a roundabout horse who by little irreverences in his behavior demonstrates that his current role does not correspond to his 'true,' 'more adult' self.

In *Stigma* (1963), Goffman differentiated the term 'self' in the context of an identity theory which distinguishes three types of identity in a basic sense that is still valid at the beginning of the twenty-first century: (1) social identity as a person's role set, (2) personal identity as a person's synchronic and diachronic individuality ascribed to him by observers, and (3) ego identity as a person's inner self-reference. Goffman used these concepts of identity together with the instruments of his dramaturgical approach above all in analyzing stigmatized deviations and deviants. He focused on the techniques of information control and emotion management of the stigmatized people as well as on the consequences of the stigmatization for their identities and socialization.

Total institutions

Goffman's book *Asylums* (1961a) represents an exception among his works in that it systematically goes beyond the interaction level. It describes a class of social organizations that has to do with confining, controlling and 'altering' people, such as mental hospitals, prisons, convents, homes, barracks, concentration camps, etc. However, Goffman's (1961a) investigated such 'total institutions', where the most elementary matters of course and norms of everyday interaction are broken, with the aim of exposing the interaction order and the self connected with it. Beyond that, Goffman's analysis demonstrated that total institutions form an ambivalent milieu for socialization. On the one hand they act as machinery for disciplining and normalizing behavior and interaction. On the other hand these institutions damage the moral self, e.g., self-respect and modesty, through various forms of humiliation.

Ritualizations

In his work Goffman repeatedly dealt with the moral sides of the interaction order. For Goffman the self is a moral fact which

implies rights and duties when showing respect and which can be observed in ritual practices and codes of everyday interaction. Every person appears as both subject and object of a ritual 'language,' a 'language' of politeness, decency, and tact, but also on occasion of contempt, wounding, humiliation, etc. (see Goffman, 1967).

At the end of his career Goffman elaborated his early ritual model to include ethological and frame theoretical considerations, on the basis of which he analyzed gender interactions and the interpretative patterns they are based on (see 1979). Goffman depicted gender as a combination of ritual styles of presentation representing beliefs about gender-specific essential attributes. These beliefs amount to a schematic asymmetry similar to that of the parent-child relationship. In daily interaction life and its media depictions (e.g., in advertising) men appear as superior beings to women by ritualizations of dress, physical contact, smiling, activity, etc.

Strategic interactions

For Goffman, ritualizations represented the most important social condition of profit-oriented strategic action on the level of interaction. Totally ignoring their contents, he analyzed this action within the framework of a model of strategic interaction oriented towards game theory (see 1969). The main point of departure and aim of Goffman's respective considerations were the social situation in which the subjects strive for control of the 'definitions' of the other players or rivals. Following on from his dramaturgical approach, Goffman above all investigated the conditions of competence and limits of 'impression management,' the strategically relevant interpretations of expression (e.g., of the body), the logic of reciprocal strategic observation and assessment, as well as the complexity of meaning and virtuosity of strategic moves. The empirical basis of the investigation consisted in particular in self-descriptions by a wide variety of strategic subjects (spies, confidence tricksters, adulterers, politicians, etc.). Goffman 'translated' their practical knowledge of action (knowledge of cleverness) into the categories of his analytic description, e.g., a typology of strategic moves.

Frames and framing subjects

Frame Analysis (1974) can be regarded as Goffman's main theoretical work, because it integrates, or could integrate, the many various analytic perspectives and terminological distinctions of his earlier works. *Frame Analysis* itself therefore forms something like a frame. It is characterized by two basic orientations. On the one hand, the interest is directed at 'structures' and procedures for establishing meaning which are effective in generating normality in social situations and which are valid, independent of these situations. On this level, which can be compared with the grammar of a language, Goffman revealed basic types of meaning and complex possibilities of transforming meaning (play, experiment, demonstration, etc.). On the other hand, on the level of the concrete situative events he aimed both at normal uncertainties, dangers, and the pressure to conform, as well as at extreme forms of abnormality, such as the 'negative experiences' of inmates of mental hospitals, whose habitual framings, which have proved their worth in everyday life, fail in the institution. The individual, whom Goffman revealed as the subject of the framing, is characterized by enormous powers of judgment and virtuosity, particularly in functionally complementing rules and also in manipulating them.

Forms of talk

In his last period, Goffman built on earlier studies and particularly concerned himself with conversations. The main result of this work is his book *Forms of Talk* (1981), which Goffman specifically placed in the context of *Frame Analysis*, one chapter of which was already devoted to conversations.

Goffman's late focusing on conversations can be seen in connection with the emergence of conversation analysis as a branch of ethnomethodology, which he approved of, but also criticized (see Bergmann, 1991). In contrast to conversation analysis, which tends to conceptualize the process of communication as an autonomously organized system, Goffman stressed the importance of ritual order, which is always culture-specific and which permits selves and consequently psychological states to develop. Goffman basically rejected the assumption by conversation analysts that sections of a conversation can be analyzed without reference to their situational and extra-situational contexts. Moreover, Goffman was mainly interested in a sociological approach to the contextuality of social processes. *Frame Analysis* represents this approach.

Goffman's Methods

Goffman's work is essentially the result of the author's talents, in particular his personal sensitivity, the subtlety of his powers of observation, and his ability to classify his material in his search for order. He displayed these talents in the course of practical research, which struck most observers as unconventional, even puzzling. Among the most irritating points are Goffman's data, whose heterogeneity can hardly be exceeded. In his works the reader comes across personal everyday experiences, novels, autobiographies, the daily press, essays by film critics, photographs, etc. In many other respects Goffman also deviated from the normal forms of sociological discourse. He abbreviated the traditional terminological vocabulary of his field, avoided lengthy argumentation, frequently changed perspective, focused on seemingly unimportant details, commented in an autoreflective manner on his own work, made ironic remarks and repeatedly told or referred to 'stories.' What is most important is that Goffman did not conform to any methodological canon, rather his methods entirely depended on the subject. This meant first of all that it was necessary to forgo certain traditional research methods. For example, the fact that those patterns of behavior that interested Goffman were generally unconscious ones meant that interviews were largely or totally impossible.

Goffman himself described his procedure as primarily 'naturalistic.' The scope of what he meant by that ranged from 'participant observation' (even in his own everyday life) to work with audio-visual recordings. His aim was always to get as close as possible to 'social nature' and to capture it as accurately as possible. On the other hand Goffman tried to achieve analytic distance and obtain information by various forms of 'alienation.' Alongside systematic work with models such as that of the theater, his most important technique was the strategy of alienation, which Paul Drew and Anthony

Wootton (1988, p. 7) called 'the investigation of the normal through the abnormal.' Goffman employed totally different forms of abnormality, such as stigmatizations, espionage, accidents, or celebrities as approaches to the logic of everyday normality.

In order to convert into texts the results that were generated by his methodological dialectic of approaching and distancing Goffman combined two strategies. On the one hand he developed a formal analytical language which contains the basic features of the interaction order and the self connected with it. On the other hand he employed a strategy of 'thick description' (C. Geertz). By using a literary style, a metaphorical language suited to the specific subject, and extensive quotations from his material, cleverly combined with his analytical observations, he succeeded in making his subject appear alive and viewing it in a new light.

Goffman's Importance for the Social Sciences Today

It is not easy to judge how relevant Goffman's work is for the social sciences at the beginning of the twenty-first century; its main significance probably lies in his contribution to discovering the interaction order. In this way Goffman opened up a specific research area and at the same time provided central categories and strategies for exploring it.

But quite apart from interaction sociology, Goffman also had a strong influence on a number of other research areas and he remains influential today. This is especially true of many aspects of research into identity and socialization. Of prime importance among them are Goffman's reflections on institutional control and discipline procedures, and on subjectivity. Goffman is especially appreciated today in research on normality and deviation as well as in gender studies, where some of his works are still standards now. In addition, he has a significant influence not only on the level of the everyday interaction order, but also on the sociology of certain social fields of action (politics, advertising, science, etc.) and in media research, where many of Goffman's analytical instruments have proved to be valid. Furthermore it can be seen that recently Goffman's works have increasingly been read and discussed from the point of view of general theories of civilization and society. For example, parallels have been drawn and connections made with the works of Norbert Elias (*see* Elias, Norbert (1897–1990)), Michel Foucault (*see* Foucault, Michel (1926–84)), and Pierre Bourdieu (see Willems, 1997). In general it is a remarkable fact that widely differing and contrasting schools have incorporated parts of Goffman's works. The spectrum of positions Goffman is 'relevant' for, ranges from modern systems theory through critical theory, right down to the rational-choice approach.

Just as the reactions to Goffman's work have been wide-ranging and many-sided, so evaluations of its scope and its identity have differed greatly. While most people see the importance of Goffman's work essentially on the level of empirical micro-observation, others (e.g., Anthony Giddens) believe that in it there is to be found a systematic theory that goes beyond the level of micro-sociology and is highly significant for the development of the social sciences. Similarly, various labels have been attached to Goffman's thinking (symbolic interactionism, phenomenology, role theory, structuralism, ethnomethodology, etc.).

No matter how the situation of his reception is to be judged, it cannot be denied that Goffman left behind a series of studies that are still relevant and influential today and a network of concepts that is both highly complex and highly integrated. Perhaps an equally important part of his legacy is the paradigm he provided by the style and ethos of his research.

Abstract

Goldthorpe's theoretical orientation involves a rejection of liberal and Marxist forms of historicism. It focuses on social patterns that can be established on a probabilistic basis and the manner in which they are created, sustained, and modified through the action and interaction of individuals. His macro- and microsociological concerns are combined in a wide-ranging exploration of multidimensional relational structures of inequality and the extent to which they result in people living in different social worlds.

Biography

John Goldthorpe was born in Yorkshire in 1935. He completed an undergraduate degree in history at University College London in 1956. In the same year he became a research student in the Department of Sociology at the London School of Economics (LSE). After 3 years as an assistant lecturer in the Department of Sociology at the University of Leicester he was appointed to a Fellowship at King's College Cambridge in 1960. In 1962, Goldthorpe and David Lockwood initiated what became known as the *Affluent Worker Study*. In 1969 Goldthorpe was appointed as Official Fellow of Nuffield College, Oxford. In the same year he was appointed the editor of *Sociology*, the newly established official journal of the British Sociological Association and became President of the Sociology Section of the British Association for the Advancement of Science.

In 1972, members of the Nuffield Social Mobility Group undertook a major enquiry into patterns of mobility of men in Britain. The findings from Goldthorpe's work were consolidated in *Social Mobility and Class Structure in Modern Britain* (1980/1987) published by Oxford University Press (OUP). His research on mobility was extended in the Comparative Analysis of Social Mobility in Industrial Nations project. The outputs from Goldthorpe's collaboration with Robert Erikson were consolidated in the landmark volume *The Constant Flux* published in 1990 by Clarendon Press. This work had a critical influence on the work of the Research Committee on Social Stratification of the International Sociological Association of which Goldthorpe acted as Vice President from 1974 to 1982 and as President from 1982 to 1985 and the European Consortium for Sociological Research (ECSR). Goldthorpe was a founding editor in 1985 of the *European Sociological Review*. In 2000, OUP published the first edition of *On Sociology* a collection of papers dealing with key theoretical and methodological issues particularly as they relate to the integration of theory and research. An extended two-volume edition was published by Stanford University Press in 2006.

Goldthorpe is an Emeritus Fellow of Nuffield College, Oxford, and a Distinguished Research Fellow at the Department of Social Policy and Intervention, University of Oxford, a Fellow of the British Academy, a Member of Academia Europea, and a Foreign Member of the Royal Swedish Academy of Sciences. In 1992, he was made a Commander of the British Empire (CBE) for his contribution to the advancement of the social sciences.

In what follows we will consider Goldthorpe's theoretical and methodological contributions before proceeding to a consideration of his substantive work in relation to social stratification and an overview of his contribution to sociology.

Theoretical Orientation

Macrosociological Perspective

As Gallie (1990: 29) observes, much of Goldthorpe's work can be seen as a prolonged engagement with the liberal theory of industrialism. Goldthorpe's (1971) critique involves a rejection of 'historicism' and a focus on its failure to specify the linkages between economic change and social action. Goldthorpe (1992) focuses on its neglect of the constraints deriving from relations with other nations, multinational business enterprises, and supranational agencies and those associated with structures and processes expressing established relations of power and advantage.

Social Action

The social action perspective employed in the *Affluent Worker Study* involved the worker's definition of the work situation becoming a key explanatory variable (Goldthorpe et al., 1968a: 26). Central to this approach was the assumption that workers inject certain meanings into the work situation, the sources of which pertain to some significant extent to the individual's wider life situation.

More recently Goldthorpe (2006a: 139–152) spelled out the key elements of his approach to a theory of social action. These include a commitment to methodological individualism; the belief that analytic primacy lies with the intended and unintended consequences of individual action. Goldthorpe (2007a: 140) argues that the appropriate phenomena of concern for sociologists are social patterns established on a probabilistic basis. The explanatory task of sociology he argues, following Boudon (1990) and Max Weber, is to show how they are created, sustained, modified, or disrupted through the action and interaction of individuals. Goldthorpe (2006a: 142) notes that Rational Action Theory (RAT) may

be understood as of an 'outcome-oriented' kind in which certain requirements are met regarding the nature of actors' goals, their beliefs relevant to their pursuit, and the courses of action which they then follow. Goldthorpe (2006a: 158–159) argues that, in relaxing the assumptions of the version of RAT employed in mainstream economics, the key idea that sociologists must exploit is that of *subjective* rationality. Actors may hold beliefs and pursue courses of action for which they have 'good reasons' in the circumstances in which they find themselves, even though they may fall short of the standard of rationality that utility theory would presuppose. The social structuring of knowledge should be treated as a crucial aspect of the situation. (The long-term consistency of Goldthorpe's position in this regard can be seen by considering his 1973 critique of ethnomethodology.)

Methodological Issues

For Goldthorpe (2004) the primary goal of sociology as social science (SSS) is the explanation of opaque social phenomena. He sees a natural relationship between SSS and descriptive sociology because of the role of the latter in establishing social regularities, particularly given the mutability of social phenomena. In a related fashion, Goldthorpe (1996) directs attention to the potential offered by the application of RAT to the quantitative analysis of large scale data sets. Statistical analysis plays an important role in defining the 'objects of study' of sociology, in conjunction with the concepts that sociologists employ.

Goldthorpe's (2001) preferred the style of sociology that is linked to his understanding of the relevance of different conceptions of causation. He distinguishes between causation as robust dependence, consequential manipulation and, his own preference, as a generative process. Further crucial distinctions relate to establishing the phenomenon, hypothesizing the generative process, and testing hypotheses. Goldthorpe (2012) stresses that while statistically analysis plays an important role in establishing sociological explananda, it cannot in itself lead to causal explanations of these regularities. Furthermore, he argues that if such explanation is the primary objective, then the counterfactual approach to causation will be of much reduced relevance.

From this perspective, Goldthorpe (2006a: 1–40) seeks to identify common methodological problems in qualitative styles of sociology. These included what he labels 'grand' historical sociology. However, he stresses that his objective is not to launch an all-out attack on such qualitative research. Rather he seeks to establish three specific points.

The first is that qualitative styles of sociology face methodological problems that their proponents largely neglect. These relate to the reliability and validity of the kinds of data on which chief reliance is placed and the manner in which they are used in the processes of theory construction and evaluation. Goldthorpe argues that claims to avoid complicity with 'positivistic' approaches lead their proponents into positions of an ur-positivistic kind. For 'grand' historical sociology this relates to a failure to acknowledge that historical fact involves inference from finite and incomplete artifacts. For case-oriented macrosociology his concerns relate to issues involving determinism vs probabilism and the failure to acknowledge the distinction between description, explanatory theory, and testing. These concerns are linked to the failure to acknowledge that the small *N* problem is one not of method but of insufficient information. He stresses the need to distinguish between recurrent social situations and processes that might be the subject of sociological theory and contingencies, distinctive conjunctures of events, or other singularities that such theory cannot comprehend.

Finally, Goldthorpe focuses on the problem that comparative macrosociology shares with ethnography arising from the difficulties associated with generalizing from insufficient samples by resorting to entirely deterministic or logical methods of analysis by invoking theory that presupposes knowledge of law like relations. Ultimately, he argues, it is necessary to deal with principles of selection and representativeness if one is to be in a position to answer the question relating to cases of *what*? (For a robust debate on Goldthorpe's views on comparative macrosociology see the collection of papers included in *The British Journal of Sociology*, 45. 1 March 1996.)

Social Stratification

Goldthorpe's macro- and microsociological concerns have been combined in his focus on a wide range of theoretical and substantive issues relating to the multidimensional nature of social stratification. His insistence on the contingent nature of the relationships between forms of stratification and their consequences forms a crucial part of his debates with theories of convergence, whether liberal or Marxist. Goldthorpe has consistently rejected reliance on 'umbrella' concepts of social stratification and synthetic indices. As Goldthorpe (2008: 352–353) makes explicit, his starting point does not invoke some counterfactual society but rather the existence a capitalist free market society. His program of social stratification research has involved in developing an understanding of the relational structures of inequality and their implications for different domains of social life.

Class and Status Analysis

For Goldthorpe, class analysis has as its central concern the relationships between class structures, mobility inequalities, and action. The focus is on the consequences of differentiation in employment relations for life chances and choices or, as Goldthorpe (2008: 352) puts it, the extent to which they result in people living in different social worlds. The objective is to investigate the interconnections between historically formed macrosocial structures and everyday experience. No assumption of the preeminence of class is required. No historicist assumptions are entailed nor do they require a theory of exploitation (Goldthorpe and Marshall, 1992: 382–383).

The class schema central to the pursuit of this agenda emerged from his work on social mobility. Its importance is reflected in its adoption as the basis of the British National Statistics Socio-Economic Classification and the European

Socio-economic Classification. Formalization of this schema, following Erikson and Goldthorpe (1992: 35–47) and Goldthorpe (2006b: 101–124), is based on two main principles of differentiation. The first is that of employment status. The second relates to the regulation of employment as a viable response to the weaker or stronger presence of monitoring and asset specificity problems in different work situations.

Goldthorpe addresses the theoretical question of how differences in employment relationships arise by drawing on RAT, particularly as employed in organizational and personnel economics. The general problems of the employment contract he argues relate to work monitoring and human asset specificity. The particular form in which they arise in terms of the principal–agent relationship is with regard to work monitoring of professional and managerial employees whom the employer engages the employee to act in the principal's interest in circumstances in which the agent's actions cannot be observed. The solution is sought in a diffuse exchange of services in return for compensation in which prospective rewards play a crucial role. This provides the basis for secure investment aimed at increasing employees' organization specific skills. The key distinction in relation to the latter is between regulation occurring via a 'labor contract,' involving a relatively short-term and specific exchange of effort for money, or a 'service' relationship, as typified in the kind of contract typical for professional staff, which involve important prospective rewards (Erikson and Goldthorpe, 1992: 41).

Goldthorpe (2006b: 120–124) notes that such differentiation is consistent with the assumption that employers will endeavor to modify contracts to shift the balance of risk toward employees. However, he is not persuaded by the arguments that globalization has led to service-type relationships being discontinued to a degree that undermines the significance of class (Goldthorpe, 2006a,b: 100–107, 122).

His approach involves an emphasis on social relations rather than individual attributes. The distinction between class and status is crucial. Goldthorpe argues that, while scales of social standing can be interpreted as indicative of general desirability of occupations, they cannot be seen as capturing social relationships of deference, acceptance or derogation (Goldthorpe and Hope, 1974). Status he understands as being expressed in differential association, especially in more intimate forms of sociability and lifestyles of differing distinction (Chan and Goldthorpe, 2007a: 1096–1097).

Goldthorpe (2008: 350) stresses the need to keep the measurement of social class independent of outcomes which it is intended to explain and of other dimensions of stratification to which we may wish to compare its explanatory power. Goldthorpe (2010) elaborates on the consequences of the failure to make such distinctions in his critique of the argument by Wilkinson and Pickett (2009) that income inequality has a negative impact on a range of social outcomes for all members of unequal societies. Goldthorpe notes that their understanding of the mechanism through which negative social outcomes are generated is crucially dependent on the existence of a close link between income inequality and social status but their failure to understand the complexities of this relationship leads them to inferences of a questionable kind.

Social Mobility

Goldthorpe (1980/1987) exploited developments in log-linear analysis that allowed for the reformulation of the exchange/structure distinction in terms of absolute mobility rates and relative chances of mobility. He proceeded to demonstrate that continuous economic growth, large-scale educational reforms, and the transformation of the division of labor were associated with the expansion of the salariat and substantial levels of absolute mobility. However, no significant reduction was observed in relative class advantages. Given Goldthorpe's explicit concern with the implications of extensive 'recruitment from below,' it is puzzling that one of the major criticisms of his work has been its supposed neglect of absolute mobility and structural change. This is so despite the fact that a focus on changing patterns of absolute mobility is central to Goldthorpe's critique of recent attempts in the UK to politicize social mobility issues (Goldthorpe and Jackson, 2007; Goldthorpe, 2012).

To understand this response it is necessary to return to Goldthorpe's understanding of what constitutes an appropriate explananda for sociology. Goldthorpe (1990: 417) argues that occupational change must be treated as 'exogenous,' permitting only description rather than explanation. It is not that Goldthorpe considers the relative mobility as more important than the absolute mobility but rather that he sees the former as constituting the kind of opaque regularities for which sociologists should seek to provide theoretical explanation.

Similarly, while Goldthorpe acknowledges that gender stratification in the labor market operates to the advantage of men, he sees the task of explaining such segregation and its impact on the class structure as lying outside the realm of class analysis. A choice must be made whether to allocate class position on the basis of individual attributes or on information available for the family unit or household as a whole. Adopting an individual approach has the consequence that women are observed to experience substantially greater downward mobility (Erikson and Goldthorpe, 1992: 239–245). The issue which arises is whether such differences should be taken at face value, in the context of the segregation of women into lower-level occupations together with discontinuous work histories. Adopting the individual approach requires accepting that women's class positions are less closely associated with their material circumstances, that their propensity for class-based partisanship is significantly lower and their class identification far more uncertain. The alternative interpretation is that it is rational and intelligible that women, whose partners occupy superior class positions, should regard their class interest and affiliations as being, in important respects, determined by their partner's employment (Erikson and Goldthorpe, 1992: 252). (For a detailed discussion of the debate in British sociology on gender and class mobility see Mc Rae, 1990.) Where class is determined by the occupational position of the member regarded as dominant in terms of work time and position, 'complete' mobility tables provide results that do not diverge significantly from those for men only tables (Erikson and Goldthorpe, 1992: 371).

The distinctions between absolute and relative mobility and between sociological and historical forms of explanation are

central to the extension of Goldthorpe's social mobility concerns on a comparative basis. This work forms part of his sustained critique of liberal industrialism which represents high and rising levels of mobility and openness as functional imperatives of industrial development. Erikson and Goldthorpe (1992) showed that industrial societies exhibited substantial variation in absolute mobility rates but that there was no support for convergent rates of such mobility or steadily increasing rates of upward movement. The observed variation in absolute mobility rates was not found to be amenable to explanation in sociological terms. Neither do the findings support the expectation that in relative rates tend to become more equal (Erikson and Goldthorpe, 1992: 253–277).

Extending such analysis, Goldthorpe focuses on the barriers to meritocracy involving countervailing class forces integral to any capitalist market society. In particular, he points to the crucial role of employers in deciding what importance should be attached to educational attainment. Goldthorpe and Jackson (2008) provide evidence of utilization of a wide variety of criteria intended to act as signals for productivity, many of which have nothing to do with educational attainment. A particularly relevant case study involves the Hungarian transition from state socialism. Bukodi and Goldthorpe (2010) examine this transition from two competing perspectives which they label as 'meritocracy as functional imperative' and 'market vs meritocracy.' The former sees the development of meritocracy as essential to the technological and economic dynamism of modern societies while the latter views it as incompatible, in important respects, with the principles of a free market economy and liberal democracy. None of the trends required to support the former argument were observed.

For Goldthorpe social mobility occurs within a class structure that conditions rates and patterns of intergenerational mobility through both the structure of opportunities and the typical attributes of class positions. What should be treated as common to individuals of all social classes is the objective of avoiding downward mobility. We will elaborate on this theoretical perspective below when considering class differentials in educational achievement.

More recently Goldthorpe's approach to analyzing class mobility has been criticized for operating at too macro a level and needing to be ratcheted down to the occupation level where 'real' social groupings emerge (Jonsson et al., 2009). Goldthorpe (2002) challenges the assumption that the study of the processes through which economic categories become real social groupings is the *sine qua non* of class analysis. Nor does he share the assumption that collective action has to proceed on the basis of transformation of class in itself to class for itself. His concern with class organization has focused on the levels at which interests are aggregated and the issues raised by the potential role of trade unions in corporate and social partnership (Goldthorpe, 1984). (The complexities of the relationships between occupational communities, images of society, and voting behavior were at the heart of *The Affluent Worker* study. Goldthorpe (1974) drew attention to the possibility that the consequences of inequality might be reflected not in class conflict but in a situation of Durkheimian anomie.) Erikson et al. (2012) conclude that the microapproach accounts for immobility rather than mobility and is substantially less successful in doing so for women. To be persuasive it needs to specify a mechanism that accounts for mobility and immobility. They accept that class analysis may not capture the highly specific processes involved in occupational mobility but they argue neither does the microclass approach, because they appear to be structured far more by father's class rather than father's occupation within class.

Class Analysis and Educational Inequalities

Goldthorpe (2006b: 21–44) notes the theoretical problems constituted by persisting class differentials in educational attainment are thrown into sharp relief by the reduction in gender differentials. Goldthorpe's explanatory account involves the development of an RAT which involves only features of class that derive directly from employment relations and avoids reference to class values, norms, and forms of consciousness. Two related arguments are involved in the initial explanatory propositions. Class differentials have been maintained because so too have the corresponding perceived differentials in costs and benefits. The consequence is that children in disadvantaged families require a greater assurance of success. Aspirations are understood in relative rather than absolute terms. Differences in choices are seen to reflect corresponding 'social distances' that must be traversed from differing class origins. This is consistent with the evidence that class differentials persist even when ability is held constant (Breen and Goldthorpe, 2001). The declining influence of costs is part of the explanation of growth in the number of children remaining in education beyond the compulsory period. However, for those from less advantaged class origins to choose to stay on at a more rapidly increasing rate than others would require a shift in *relative* risks and costs. The fact that gender disparities have been largely eliminated suggests a more positive cost–benefit evaluations of education for women in the light of changing gender relations and labor market conditions. The role played by gender differentiated patterns of inheritance also helps to account for the different choices made by the self-employed for sons and daughters.

Following Boudon (1974), Goldthorpe distinguishes between 'primary' and 'secondary' effects. The former captures the relationship between children's class origins and their average levels of demonstrated academic ability. Secondary effects operate through the decisions made by children and their parents regarding particular educational options.

Goldthorpe (2007b: 29) accepts that the degree of congruence between the subcultures into which children are socialized and those that prevail in schools can contribute to accounting for educational differentials. However, to explain persisting differentials it would be necessary to provide an account of how such cultural influences have maintained their differentiating power in the context of social transformations involving major educational expansion and reform. Goldthorpe (2006b) notes that Bourdieu's (1973) theory of 'cultural reproduction' offers such an explanation. 'Dominant classes' impose a pedagogy which requires of children an initial socialization into the 'dominant' culture. Educational inequalities are maintained by

unequal amounts of, largely arbitrarily defined, 'cultural capital' transmitted over a longer period than economic capital and with less possibility of reversibility.

Goldthorpe argues that this account founders on the predominance of 'first-generation' students entering more selective and academic forms of education during the post-war decades. With expansion and reform, the constraints on choice that primary effects impose tend to weaken and greater scope is created for the impact of secondary effects, as reflected in educational choices. It is assumed that, in their central tendencies, such choices can be understood as reflecting evaluations of the cost and benefits of possible alternatives. Three mechanisms contribute to the emergence of class differences. These comprise relative risk aversion, differences in ability, and expectations and resources. The expectations derived from this model differ from those associated with standard human capital theory in which class differences are viewed simply as the result of corresponding differences in average ability and resources. However, they contrast even more sharply with sociological explanations in which cultural capital is the key explanatory factor.

Goldthorpe (2008: 31) distinguishes between cultural resources and cultural values in order to accommodate class differences in the former that are necessary to the realization of values that are largely shared. From this perspective, the tendency of children from working class families to pursue less ambitious careers is not necessarily a consequence of poverty of aspirations but arises from the differences in 'social distances' that must be traversed. This approach allows a role for choice in relation to secondary effects that is conditioned by a structure of opportunities and constraints (these include not only social class of origin but also parental class and parental education and status (Bukodi and Goldthorpe, 2013)) including class variation in evaluations of risks and rewards. However, such choice involves more than the expression of unchanging and compelling subcultural values and norms (Goldthorpe, 2006b: 80–81). (For a robust set of exchanges on Goldthorpe's critical comments on Bourdieu's interpretation of class differentials in educational attainment see the contributions to *Sociologica* 2007, 2 and 2008, 1.)

Cultural Consumption

Chan and Goldthorpe (2007b) identify three rival lines of argument in the current sociological literature dealing with the relationship between social stratification and cultural taste and consumption. These comprise the homology, individualization, and omnivore–univore arguments.

The homology argument claims that social and cultural stratification map closely on to each other. Individuals in higher and lower social strata, respectively, prefer and predominantly consume 'high' or 'elite' culture, and 'popular' or 'mass' culture. For Bourdieu (1984) class and status are not to be understood as different forms of social stratification, rather status is the symbolic aspect of the class structure which is not in itself reducible to economic relations. The individualization thesis holds that differences in cultural taste and consumption are losing their grounding in social stratification and are becoming more a matter of individual 'self-realization.' In contrast with Bourdieu's position, the emphasis shifts from habitus to freedom. The omnivore–univore argument advances the hypothesis that the cultural consumption of individuals in higher and lower strata differs chiefly in comprising not only more 'high-brow' culture but also more 'middle-brow' and 'low-brow' culture. The crucial contrast is not that of 'snob versus slob' but that of cultural omnivore versus cultural univore. As Chan and Goldthorpe (2007b) note, this interpretation can developed in two rather different ways which come close, respectively, to the homology and individualization arguments.

Goldthorpe and Chan's (2007b) analysis of musical tastes in the UK leads them to conclude that the homology argument is undermined by the fact that they could identify a potential 'mass' of univore musical consumers but not a musical 'elite.' Univores make up a majority of even the professional and managerial classes. At the same time, the degree of social differentiation in consumption patterns undermines the individualization thesis. Social status and education are a good deal more important than class in differentiating between univores and omnivores, refuting the claim that status is simply a symbolic reflection of class. Chan and Goldthorpe (2004) conclude that, while a status order can be discerned in present day Britain, it is less sharply demarcated than previously with status differences being less openly asserted from above and less deferentially acknowledged from below.

The Contribution to Sociology of John H. Goldthorpe

In the introduction to the first edition of *On Sociology* John Goldthorpe argued that sociology was in a state of intellectual disarray. Goldthorpe's central concerns related to a manifest lack of integration of theory and research, a collective failure on the part of sociologists to decide just what kind discipline sociology should or ought to be and an appeal to a form of pluralism that encourages cognitive relativism. These concerns were not new, as reflected in a letter to the *Times Higher Education Supplement* in July 1982 in which he bemoaned the preoccupation with types of 'theory' that are often no more than mere word spinning and the scandalous disregard for maintaining the standards of research expertise. Goldthorpe is not an uncontroversial scientist, as reflected in the title of a volume devoted to his research: *John H. Goldthorpe: Consensus and Controversy*. Here we have referred to the vigorous debates in which he has been involved relating to macrosociology, RAT, gender, mobility, and cultural capital. These exchanges reflect the fact that even those who most vehemently disagree with his conclusions understand that his intellectual standing requires that they engage with him. Goldthorpe, for his part, has taken his critics seriously but has shown himself to be consistently unswayed by intellectual fashions and has held firmly to the view that arguments have to be judged on their merits rather than by reference to the celebrity of their authors (Goldthorpe, 2007b: 1).

Goldthorpe's fundamental concern has been with the cumulative development of the discipline. His programmatic essays in *On Sociology* are focused on the development of

a kind of sociology in which theoretical and methodological discussion can reflect a genuine pluralism rather than an 'anything goes' intellectual climate. Goldthorpe has pursued this objective not only through his own research but through his roles as a colleague, mentor, collaborator, and office holder at Nuffield College, the European Consortium for Sociological Research and the Research Committee on Stratification of the International Sociological Association (ISA).

Goldthorpe's approach is not intended to promote a school of sociology, Thus, Goldthorpe (2006b: 81–82) has responded to the critiques of his development of RAT for sociology as 'antisociological' with a clear statement that theories have to be judged not by their provenance but by their consequences in terms of whether or how far they lead to adequate explanations and stand up to empirical test. Goldthorpe's approach to such micro–macro linkage has had at its center issues relating to the social structuring of knowledge and the need to understand the logic of the situation from the actor's point of view. From a macro perspective, in rejecting historicist perspectives in both their functionalist and Marxist forms, he has consistently emphasized the importance that should be attached to historical and political contexts and choice. There is no need Goldthorpe (1992: 431) stresses to accept that constraints of whatever kind operate in a manner that issues relating to purposive social action and what the future *could*, as opposed to *should*, look like become irrelevant.

Goldthorpe has consistently argued that sociology will benefit from confronting problems that arise exogenously and that require a focus on causes of effects rather than 'cherry-picking' problems chosen to illustrate the power of some generative model by a concentration on 'effects of causes' (Goldthorpe, 2001: 102–103). The danger of the latter approach he argues is that it can give rise to a greater interest in mechanisms per se than in the actual extent of their explanatory potential.

Following Merton (1959), he has stressed the ultimate complementarity of pure and applied science. Being able to show that problems have a 'double rationale' in terms of internal scientific development of sociology and applied importance provides protection against what he refers to as 'sociological dandyism': a preoccupation with models on account primarily of their intrinsic elegance, refinement, and subtlety (Goldthorpe, 2001: 100–101). Goldthorpe's own research achievements provide a perfect example of the manner in which rigorous theoretical development and methodological sophistication can be combined to produce a body of sociological work that is of major substantive relevance from the standpoint of both pure and applied interests.

Abstract

André Gorz, who was born in Vienna but adopted France, was a French public intellectual and philosopher. Heavily influenced by the alienation brought on by National Socialism experienced during his younger years, his perspective is described as that of an existential Marxism influenced by Sartre. An advocate of a political ecology that combined critique of capitalism with environmental concerns and the importance of liberty, he was a leading philosopher in the French *Nouvelle Gauche* (New Left). Known as a philosopher under the pen name Gérard Horst, he published as a journalist under the pen name Michel Bosquet.

Life

André Gorz (pen names Gérard Horst and Michel Bosquet) was born in Vienna on 9 February 1923 and named *Gerhart Hirsch*, was the son of a Jewish timber trader Jakob Hirsch and a Catholic secretary from Dresden, Maria Hirsch. Owing to the pronounced anti-Semitism in Austria, Gorz's father converted to the Catholic faith in 1930 and the family assumed the 'Aryan' sounding surname (Robert) Horst. As a school pupil, Gorz, who had not experienced any Jewish religious or cultural instruction, was at first attracted to the 'vital values' that ironically National Socialism seemed to him, from a distance, to embody. The central motif of Gorz's life and work, namely the issues of doubt and change surrounding identity, had its roots in this early experience: "I began to lose my identity when one of my dear school buddies showed me a poster on which there was an illustration of a Jew with locks of hair hanging from the temples, a crooked nose, dribbly lips and hook-like fingers and said: that is your father! From then on I knew I was not a normal person and that, in the eyes of others, I was neither an equal nor of equal worth" (Leggewie, 1989: 17). The experience of having a pariah identity as a second-class Jewish person forced upon him by the majority society was one that Gorz shared with many of Europe's assimilated Jews.

Encouraged by his mother, who wished her son to be spared the ordeal of military service, Gorz attended 'Montana' boarding school in the Swiss canton of Graubünden one year after the annexation of Austria into the German Reich in 1938. Here, he assumed the name Gérard Horst. Upon graduation, he commenced the study of chemistry at the engineering college in Lausanne and began to write philosophical essays, stories, and political articles for the newspaper of a Swiss cooperative. Thus, he began his career as a freelance author, and the onset of the feeling of existential emptiness and political homelessness that caused Gorz to seek refuge in *république des lettres* (the *Republic of Letters*, i.e., a long-distance intellectual community).

In politically neutral Switzerland, Gorz experienced the scarcely concealed complicity with the fascistic *weltanschauung* of Hitler's Germany. As France was overrun by the Wehrmacht's *Blitzkrieg* ('*drôle de guerre*') and occupied in the northwestern part, he made this 'emptiness' the anchor of his personal and political identity – an existentialist design for an 'other,' imagined identity: "[…] when I learnt in 1940 that France had collapsed under the triumphant progress of the *Wehrmacht* and the 'master race,' I had the feeling that, yes, these are the people to whom I am closest. France is sinking into nothingness and it is in this nothingness that I shall declare my faith […]" (Leggewie, 1989: 17). With the political obliteration of the French Republic, which had collaborated with the Germans in the form of the fascistic Vichy regime, Gorz chose literary and philosophical France as his spiritual home for the period until 1946, during which he remained physically in the Swiss confederation: that is, neither the United States, which lent itself as a site of exile for many others who experienced a similar destiny, nor Stalin's Soviet Union (both of which would anyway have been, on a practical level, out of reach for the young Gorz).

Gorz's pattern of socialization during the interwar period was (not so) extraordinary: the Jew and secret admirer of 'vital' National Socialism in anti-Semitic Austria was brought up by a governess in the French language, became a half-Jew in the extended German *Reich*, then a Jew with a German passport in a Switzerland that had complied to the *Reich* and, finally, converted to a geographically displaced but biographically and linguistically rooted Frenchman. "France has never been a nation in the German sense of the national, that is, the reason that one turns to French culture as a foreigner has not to do with thoughts concerning the national but with the universality of French culture" (Leggewie, 1989: 20). This virtual naturalization was fleshed out through Jean-Paul Sartre, who during the occupation had begun his ascent toward becoming the country's leading intellectual. Gorz devoured Sartre's novels and works for theater, and also personally met with him during Sartre's lecture series in Switzerland.

It was also in Switzerland that Gorz met his wife, Doreen, who was a Scot by birth and with whom he would spend the rest of his life. The couple departed for Paris in 1949, where Gorz commenced his profession as a freelance writer in the proverbial attic digs. He earned his living as a secretary to the 'Citizens of the World,' a cosmopolitan society initiated by the American Gary Davis, a peace activist who created the *World Passport*, the first travel document originally based on world citizenship, and as a press agent at the Indian embassy, before becoming active as a journalist. It was upon joining the *Paris-Presse* newspaper that both his pseudonyms came into being under which the author and philosopher Gérard Horst would become renowned worldwide. While the journalistic alias Michel Bosquet was one possible translation of 'Horst' (small

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61207-2

wood) into French, the philosophical *alias* author of the first great work, *Le Traître* (1957), stemmed from a childhood memory of his father's military telescope, manufactured in the then Austrian town of Görz. This central European border town, located on the border between Austria, Italy, and Yugoslavia, was of particular interest as concerns the three names André, Michel, and Gérard, since, after 1919, the town assumed three linguistic identities: Italian Gorizia, Slowenian Gorica, and Friulian Gurize. Bosquet was now the name of the journalist, Gorz that of the philosopher, and both answered to the name in the passport of Gérard Horst.

After this elaborate self-construction, due to the complicated course of his time, the remainder of André Gorz's life story is cursorily outlined in the following paragraphs.

In 1954, Gorz, stateless until then, became a French citizen – apparently thanks to the support of the French politician Pierre Mendès (Contat, 2009). The following year, 1955, Bosquet took up the editorship of the left-liberal weekly magazine L'Express, following which, in 1964, he joined the editorial team of France Observateur, which was still more left-leaning, and later became Le Nouvel Observateur – of which Gorz was acting editor-in-chief until 1983. Following the publication of his philosophical novel *Le Traître*, with a forward by Jean-Paul Sartre, the philosopher Gorz in 1961 joined the editorial committee of the monthly magazine Les Temps Modernes, where he remained until 1974.

The 1960s saw the generally introvert Gorz become a 'public intellectual' and a leading intellectual force of the New Left. Apart from numerous articles in the aforementioned journals (and many marginal leftist reviews), his status was above all established by the books, of which there were many reprints as well as translations into numerous languages: S*tratégie ouvrière et néocapitalisme* (Editions du Seuil, 1964), *Le Socialisme difficile* (Seuil, 1967), and *Réforme et Révolution* (Seuil, 1969) (see Part 2). Subsequent to this phase, during which an alternative to the Communist Party presented itself (Gorz sympathized with the ex-Catholic, increasingly left-leaning, moderately anarcho-syndicalist CFDT (*Confédération française démocratique du travail*) and the left breakaway party PSU (Parti Socialiste Unifié)), there came works that were just as influential in a field to which Gorz contributed much: political ecology. These works are *Critique du capitalisme quotidien* (Editions Galilée, 1973), *Critique de la division du travail* (Seuil, 1973), *Écologie et Politique* (Galilée, 1975), and *Écologie et Liberté* (Galilée, 1977). Neither should the role of Bosquet in the founding of the ecology magazine *Le Sauvage* (1973ff.) be forgotten. As regards German-language publications, Bosquet also provided the idea for the series *Technologie und Politik* under the general editorship of the Hamburg publicist Freimut Duve and published by Rowohlt Verlag.

In the 1980s, Gorz became a reluctant supporter of the Union de la Gauche, which, under Francois Mitterrand, had found its way into power. At the same time, unlike a series of so-called *nouveaux philosophes*, he did not turn away from Marxism. In the publications that then appeared, beginning with the bestseller *Adieux au prolétariat* (Galilée, 1980; Le Seuil, 1983), followed by *Les Chemins du Paradis* (Galilée, 1983), the work of founding theory *Métamorphoses du travail* (Galilée, 1988), and the scattered pieces collected in *Capitalisme Socialisme Écologie* (Galilée, 1991), Gorz presented an original synthesis that drew on an empirically grounded critique of capitalism, on a Marxism enriched by humanist elements and existentialist philosophy, and on political ecology. During the last two decades of his life, Gorz left the *Nouvel Observateur*'s editorial team and moved to the countryside, where he concerned himself intensively with bioethical questions of life and death, and with the changes that the Internet had prompted in society.

The book by André Gorz that sold most and captured the most attention was the slim but striking volume *Lettre à D. Histoire d'un amour* (Galilée, 2006; Gallimard, 2008), an ode to his wife Dorine concerned with the themes of his earlier works. It begins with the sentence: "Tu vas avoir quatre-vingt-deux ans. Tu as rapetissé de six centimètres, tu ne pèses que quarante-cinq kilos et tu es toujours belle, gracieuse et désirable. Cela fait cinquante-huit ans que nous vivons ensemble et je t'aime plus que jamais" ("You'll be 82 years old. You have shrunk by 6 cm, you weigh but 45 kilos and you are always beautiful, graceful and desirable. It has been 58 years that we've lived together and I love you more than ever."), and ends with the prophetic sentence: "Récemment, je suis retombé amoureux de toi une nouvelle fois et je porte de nouveau en moi un vide débordant que ne comble que ton corps serré contre le mien […] Nous aimerions chacun ne pas survivre à la mort de l'autre. Nous nous sommes souvent dit que si, par impossible, nous avions une seconde vie, nous voudrions la passer ensemble." ("Recently, I fell in love with you again and I carry inside me an overflowing void that only your body held tightly against mine fills […] We each would like not to survive the death of the other. We often said that if, in the unlikely event, we had a second life, we would like to spend it together.")

The couple ended their 'first lives' by committing suicide together on 22 November 2007. There is no gravesite devoted to them; their earthly remains were scattered to the wind.

André Gorz's papers can be found in the Institut Mémoires de l'Édition Contemporaine (IMEC) in Caen (http://www.imec-archives.com/fonds/gorz-andre/).

Works

André Gorz left behind an extensive, thematically diverse and highly influential body of work that is of astonishing relevance to many significant questions in the current debate on social theory and sociopolitical issues. It comprises voluminous philosophical works as well as short, sharp political commentaries on contemporary questions. Although both of the author's names are no longer in circulation among the majority of today's young, his influence extends today far beyond the milieu of the 'New Left' within which his writings first began to be discussed.

It is hardly possible to do justice to Gorz's *oeuvre* within such a limited space. One can however point to some of the stages in the development of his thought and identify some of the themes that, in various nuanced ways, reoccur throughout his work and to which, the preoccupation with the autonomy and freedom of the individual must be seen as central, and which Gorz considered massively threatened by the structures surrounding capitalist economy, technological development, and technocratic systems. In the 1960s, Gorz concerned himself

with the strategic options available to the workers' movement and thus distanced himself from the dogmatic positions of those hailing from the political parties of the Left, whose programs and politics he called into question – particularly where the French Union of the Left was concerned. In the 1970s, Gorz became a leading intellectual force in terms of political ecology. Thereafter, he concerned himself with the transformation of the capitalist economy and society wrought in the face of digitalization, biopolitics, and the knowledge economy, and critiqued the inhumane dimensions of this transformation, while also drawing attention to its potential outcome in a freer society.

Although most themes and points of emphasis extend throughout the body of his work, one can divide them roughly into four phases: (1) existentialist Marxism (*Traître*, *Fondements*, *Lettre à D*); (2) New Left and self-organization in neo-capitalism (from *Stratégie* to *Adieux au prolétariat*); (3) political ecology (*Écologie et politique*/*Écologie et liberté*); and (4) immaterial economy (*L'Immateriel*). Marxist sources and influences always were and remained significant; there was no departure from Marxism as described by many castigators. Continuously, Gorz read Marx's texts without ever having become 'Marxist' in any dogmatic sense (the sense that Marx himself had mocked in those who succumbed to it):

1. The influence of Jean-Paul Sartre too remains recognizable in all phases of Gorz's life and work. At the same time, Gorz's philosophical work (*Le Traître*, *Fondements*, *Critique*) did not achieve the consistency of the role models with whom he had been so impressed and whom he studied so meticulously to begin with; as such, Gorz was neither a 'Sartrean' nor an 'existentialist.' Nonetheless, motifs from Sartre's existentialist philosophy remain significant and, above all, that foundational existential motif, the treatment of nothingness, the nothingness that can appear in the devastating gaze of the other, and the resulting, lifelong sense of homelessness; then the denial of a human nature that is reified in tradition and morality, collectives and conventions, and the resulting emancipation of 'objective compulsions,' the possibility of choosing and freedom to make decisions, the emphasis on freedom; lastly, the precarity of the subject and his tendency to flee in the face of his own freedom (see Häger and Meretz, 2012).
2. Gorz was never convinced of the capitalist economy's capacity of inclusion, nor of its productivity. For him, the invisible hand of the market ruled at the expense of the human workforce, freedom, and creativity; markets were no replacement for the organizing hand that held society together. In order to be able to analyze the development, logic, contradictions, and crisis-prone nature of capitalist production and reproduction, Gorz reached for Marx's works, the three volumes of *Capital* among them. But it was the early Marx that most interested him and who dealt with the alienation implicit in capitalism. Gorz did not so much seek anti- asnoncapitalistic ways out – 'ways to the paradise' that lie beyond the dictates and the primacy of the economy (which Marxist–Leninism and actually existing socialism have never overcome).

In this sense – how liberation can succeed and socialism can be practiced (Gorz later preferred the concept of 'conviviality,' which he took from Ivan Illich since 1968) – he emerged as the speaker of the New Left in the May 1968 revolt, which was on the one hand closer to the concrete *forces vives* of dissent and innovation than the old leftist parties of socialists and communists and, on the other, overcame the collective ideology of the monolithic proletariat and recognized in the diversity of social movements the motor of a 'revolutionary reformism.'

A large portion of work dealing with Gorz's reception is concerned with the question, which in the last analysis is irrelevant, as to whether Gorz interpreted Marx 'correctly,' whether or not he was an orthodox or dissenting Marxist, or whether in a given work a revisionist turn had taken place or not. Gorz had never located himself in this Marxologic context; he did not think in terms of dogma but of problems and challenges that the times in which he lived presented. Added to which, the question, already elaborated in Marx but ignored in actually existing socialism just as it was in capitalism, of the relations between humans and nature in capitalism also featured.

3. Building on parallel patterns of thought that were critical of civilization and had accompanied industrialization from the beginning, the 'ecological question' posed itself in the 1970s with a renewed sharpness. It was by no means down to chance that answers, which may retain their validity for a comprehensive analysis conducted in the context of the cultural sciences, came from an interpreter of modern times closely associated with the existentialist philosophy of Jean-Paul Sartre. In contrast to Sartre, who was at the time in the process of becoming a literary Maoist, André Gorz, for the most part under the *nom de plume* Michel Bosquet and as acting editor-in-chief of the left weekly magazine *Le Nouvel Observateur*, turned his attention in a series of striking essays to a critical revision of Marxism (Gorz, 1980a,b,c) and the relation between ecology and politics. Gorz went beyond the environmental management that had also emerged in the 1970s and become institutionalized in policy and administration, and provided a postindustrial and post-bureaucratic basis for political ecology. Here, there are affinities with his contemporary Alain Touraine, the theorist, and participant observer of new social movements.

Collected in the paperbacks *Écologie et Politique* (1975) and *Écologie et Liberté* (1977a), both widely available in France, Germany, and other European countries, are the author's contributions to *Nouvel Observateur* and the environment magazines *Sauvage* and *Lumière et vie* during the years 1973–77. Here, the 1973 'oil crisis' as well as the critique of growth following the report of Club of Rome provided the background, along with the efforts of French and European socialists and 'eurocommunists' to create a party-political Union of the Left. The little great book was at the time read above all as a strategy paper of the environmental movement that emerged at the end of the 1970s and as a 'leftist' basis for the alternative green parties, which were at the time very heterogeneous in terms of the support, ideology, and milieus upon which they drew and which in France and Germany experienced their first success at the polls (Leggewie and Miller, 1978).

Gorz disputed the basis and the potential of every kind of politics of environmental protection that was not at the same time a guarantor of freedom for such a politics only served to perpetuate the "development of the industrial technosphere […] without compromising the self-regenerating capacities of the ecosphere. This approach does not involve a fundamental break with industrialism and its hegemony of instrumental reason"; bans, administrative regulations, taxation, subventions, and fines only lead to the regulation of society from the outside. This approach makes eco-compatibility seem obtainable "without any need for change in the mentalities, values, motivations or economic interests of the social actors." (The quotes are referred to: November–December 1993. "Political Ecology: Expertocracy versus Self-Limitation" (John Howe, Trans.). New Left Review, pp. 55–67. http://newleftreview.org/I/202/andre-gorz-political-ecology-expertocracy-versus-self-limitation.)

If these should change, and Gorz believes that they should, they would not do so as a result of some kind of authoritarian measures taken by the state, as might occur under 'green' expert rule. Rather, the protection of the lifeworld would be defined through the realization that "the result of activities corresponds to the intentions that gave rise to them; in other words, that social individuals see, understand and accept the result as the outcome of *their* actions." (emphasis CL). Just like megatechnologies (of which the nuclear state developed in France in the 1960s is exemplary), a perfected environmental management would also further the technification and colonization of the lifeworld to which the ecological movement had specifically objected. 'The system invades and marginalizes the lifeworld", in Gorz's formulation (see above), which draws upon the work of Ivan Illich and the terminology of Jürgen Habermas, as also on older traditions of *Lebensphilosophie* (philosophy of life). Thus, he describes "the world accessible to intuitive understanding, to practical and sensory assimilation. [The system] deprives individuals of the chance to have a world, to share it with one another. It was against the different forms of this expropriation that resistance gradually came into being."

Gorz thought the ecological movement was capable of overcoming the same old divisions and conflicts within industrial society that had made the 'old Left' (in France, in the form of the 'Union of the Left' on its way to taking power) the advocate of the dominant industrialism and a follower of the 'religion of growth.' "So ecologism could become a political movement after all. Defence of the lifeworld was not just a sectional, local aspiration lacking general validity, but something in tune with the interests of humanity in general and the living world as a whole" (see preceding paragraphs). For Gorz, as a natural scientist by training with a liking for engineers and statisticians, it was this that constituted the decisive advantage, in democratic and political terms, of political ecology, namely "the problem of retroactive coupling of necessity with normativeness or, if you prefer, the transformation of objective necessities into normative behaviour corresponding to needs that have been experienced, and that influence the form in which the objective necessities are perceived." This social contract for sustainable development led him, with reference to the Marxist labor theory of value and criticism of capitalism, to formulate the 'norm of sufficiency' – which he now emphasized above all as an *ecosocialist* – to which the economic rationality of capitalism stood in opposition. In arguing his case, Gorz used the example of 'the societal ideology of the motorcar.' At the core of an ecosocial argumentation: "to restore politically the correlation between less work and less consumption on the one hand, and more autonomy and more existential security on the other, for everyone."

Gorz and other social theorists further developed this approach through conceptual and practical consideration of a guaranteed basic income, in accordance with which, the connection between labor (time) and wage income would be terminated and the resulting disposable time become 'the true measure of wealth' (Marx, *Grundrisse*). "This boils down to saying that economic activity has meaning only if it serves something other than itself."

4. Gorz's understanding of the ecosocial question always went hand in hand with a radical critique of the hostility of capitalism to 'life,' which he then, however, applied 'constructively' as well in *Paths to Paradise* and the collection of essays *Und jetzt wohin?* ('And now where?'), namely with regard to the opportunities that a digitally supported and networked knowledge society offered (*L'Immatériel*); these opportunities were only achievable through a radical reduction in formal labor time and the provision of a guaranteed basic income, that is, through terminating the connection between labor and income in order to enable the people's creative potential to develop. To which he perceived modern biotechnology and gene technology as being completely opposed. At the end of his life Gorz came back to a radical critique of capitalism without ignoring the liberating elements of knowledge production in 'digital capitalism.'

Influence and Impact

André Gorz did not belong to any school of thought, nor did he actively encourage followers. He was an exemplary maverick among the intellectuals of the New Left. And he maintained an intellectual distance from the activists of May 1968 and the global student revolt too. He had never been an insider in the circle surrounding Sartre and de Beauvoir, and the vanity of the Paris star-intelligentsia made him feel acutely uneasy; he felt like a stranger among the staff of *Le Nouvel Observateur*, the magazine he himself had helped found. Gorz appeared only with considerable reluctance at public events, avoided electronic media, and fled the nervosity and blasé attitude of the metropolitan city. He was more inclined toward face-to-face conversation and the sharing of ideas within a small circle, and had a preference for publishing in lesser-known journals.

Despite his personal disposition as a maverick and a literary cultivated manner of self-presentation as an outsider, his books of the 1960s had a considerable influence on the theoretical formulations of the *Nouvelle Gauche* or New Left globally and especially on those 'green' social movements emerging from both the New Left and other alternative currents. In this respect, it was the trained natural scientist's

empirical knowledge of natural phenomena that made him stand out and eschew the romanticization of the 'environment' and its discussion in absolute terms. As in the case of another of the period's great solitary figures, Ivan Illich, central to Gorz's political ecology was the safeguarding of individual freedom and collective autonomy against the politico-economic and techno-industrial accumulation of power that was, for Gorz, embodied in the idealized 'nuclear state' (Robert Jungk).

It was this essentially antiauthoritarian, anti-institutional, and libertarian mode of thought that gave rise during the 1980s to the distance he maintained from and his criticism of the bureaucratic industrial project of the socialists and communists in the Union of the Left, and to his rejection of a dogmatic, ossified Marxism. Politically, Gorz favored the independent candidates for president – including in opinion pieces in the *Nouvel Observateur* – the agronomist René Dumont (1974) and the head of the environmental association *Amis de la Terre* Brice Lalonde (1981). Gorz did not envisage a state led by the Left that administered redistribution from above in the industrial labor society, but a qualitative change that came from within the labor society itself, through a change in the way of life that would render a postindustrial society, which would not overexploit its natural resources and exceed its physical limits.

French was Gorz's chosen language, and it was thus self-evident that he addressed, in the first instance, French readers. However, it was Michel Bosquet in particular who was listened to and read, the sharp-tongued and aggressive interpreter of his time, rather than the social and moral philosopher André Gorz, who attempted to link existential philosophy with a critique of political economy and to broaden his outlook to take into consideration the latest developments in the postindustrial society, including the knowledge commons that digital media in their capacity as sources of information and a means of communication seemed to make possible. As a political philosopher he fell between two chairs as far as the French parties of the Left were concerned, which misunderstood him by dismissing him either as a Marxist dogmatist or a post-Marxist renegade. He remained closest to the left-socialist CFDT trade union confederation and the refined PSU, which offered a home to dissenters from the workers' parties, as well as to anticolonialists and independent intellectuals of the Left; they were, to begin with, led by Gorz's special supporter Pierre Mendès-France, and from 1968 by Michel Rocard, and propagated a self-organizing socialism that came very close to Gorz's own ideas. (It must be from this affinity that the common categorization of Gorz as a 'Trotskyist' stems.) The French Greens, who could recognize in him a genuine mentor, misunderstood him to a similar extent and could not use his ideas in their programs; within France's political system they emerged as something of a lost cause, despite having been founded earlier and originally being more powerful than green movements in Germany and other European countries.

Governance

Gunnar F Schuppert, Social Science Research Center Berlin, Berlin, Germany

Abstract

What accounts for the pervasive use of the term 'governance' and to what does it refer? This article aims to answer these questions by first examining the scientific roots of the much vaunted, but often contested concept. To clarify its actual meaning, the cornerstones of an emerging governance theory are then discussed, followed by an inquiry into how governance can be viewed in the context of changing statehood. The article ends with a review of how this concept relates to broader contemporary changes in statehood, transnational decision-making, and the architecture of modern governance.

Introduction

"The word 'governance' is ubiquitous. The World Bank and the International Monetary Fund make loans conditional on 'good governance.' Climate change and avian flu appear as issues of 'global governance.' The European Union issues a White Paper on 'governance' […]. What accounts for the pervasive use of the term 'governance' and to what does it refer? Current scholarship offers a bewildering set of answers." These remarks sound like and are indeed the classic opening of an introductory chapter in the 'Handbook of Governance' (Bevir, 2011: p. 1). Considering this opening, the aim of this article is quite obvious: it seeks to clarify the concept of governance and to offer some guidance and orientations for all those who have and want to move on the slippery ground of the governance concept. To achieve this, the article proceeds in three steps: We will start with some theoretical considerations, which will help us explain what is 'new' about governance and why the governance concept is so tremendously successful. At this point, it should be hopefully clear what governance means and we can therefore continue to look at governance in the policy world, presenting three examples for 'governance at work.' Finally, we conclude this overview by discussing the strengths and weaknesses of the governance concept.

Before we start it should be made clear that we talk about public governance, not about corporate governance. Corporate governance is a field of policy and research by its own, going back on the influential publications of Ronald Coase (1937) and Oliver Williamson (1985). In these studies, they pointed out that a decisive factor for economic success and effective transactions is to be found in the organizational structure of a corporation. Corporate governance (for an overview see Jürgens, 2006) encompasses a great variety of topics: from the basic aims of private firms as market actors including their role in society (Corporate Social Responsibility), to rules of transparency in the field of financial reporting, incentive structures for managers and the structures of supervisory boards. The importance of this branch of governance is mirrored in the numerous 'Corporate Governance Codices' as guiding rules for 'good corporate behavior.' As the focus of this article is governance in the public sector, we will not go deeper into this field of corporate governance.

Some Theoretical Considerations

At the beginning of the theoretical part, the term governance should be defined. Zürn et al. (2010: p. 2) suggest a generic definition of governance that denotes "the sum of rules and regulations […] processes as well as structures, justified with reference to a public problem." In greater detail, Michael Zürn defines governance as "[…] all the collective rules which aim at a certain set of problems or a certain societal constellation and which are justified by referring to the collective interest of the affected group" (2008: p. 554).

But these definitions do not tell us, what is new about governance and what can be regarded as the added value of the governance concept. The best way to answer these questions is to contrast the governance concept with other more 'classic' concepts; we start with contrasting (**Table 1**).

The lesson we can draw from this table is, that governance is a nonstate-centered concept. One of the critical reasons for the tremendous career of the governance concept is that it overcomes the state-centered approach, which dominates many publications in governance-relevant disciplines like political science, law, and history. Furthermore, the stateless term governance seems to offer the opportunity to jettison the unloved triangle of state/hierarchy/command and control by a 'semantic coup': from state/government to governance.

And indeed we can notice the broad consensus that the governance concept must be understood as a nonstate-centered concept. Scott Burris et al. (2008: p. 2) have put this consensus as follows:

> There is fairly wide agreement that it no longer makes sense to conceive of the state as the monopolist of governance. Once it was dogma that our collective world was divided into two fundamentally different spheres: the public sphere – which was the realm of governance; and, the private sphere – the realm of the governed. This crucial distinction has eroded. States do not enjoy a monopoly on governance, and themselves are often governed by non-state actors.
>
> It now makes more sense to describe our world as polycentric, with multiple agencies and sites of governance who govern through a variety of forms of power and largely in their own interests with far reaching collective impacts. This is as true at the inter-national level (where the proliferation of non-state governing actors has been characterized as a, post-Westphalian regime) as it is at the local (where, for example, more public order services are provided by private security guards than by public police).

Table 1 Government and governance

	Government *State versus market/society*	*Governance* *State, market, and networks as complementary methods of steering*
Polity	● Focus on the state ● Majority rule and hierarchy as most important institutions	● Institutional structures combining elements of hierarchy, bargaining systems, and mechanisms of competitions ● Networks
Politics	● Competition for power between political parties and for influence by lobby groups ● Conflict solving by decisions of state agencies and implementation of state made decision	● Conflict between governing/guiding and governed/addressed actors ● Guidance and control in the context of institutionalized regulatory regimes ● Negotiations between state and nonstate actors ● Adjustment of institutional regulatory regimes
Policy	● Lawmaking (commands and bans) ● Distribution of public goods	● Independence (in networks and associations), compromises, deals ● Coproduction of public goods ● Institution policy (management of institutional change)

Source: Benz, A., 2004. Einleitung: Governance - Modebegriff oder nützliches sozialwissenschaftliches Konzept? In: Benz, Arthur (Ed. and Trans.), Governance – Regieren in komplexen Regelsystemen. VS Verlag, Wiesbaden, pp. 11–28.

In the same direction argues Christoph Zürcher looking from the outside at the problems of governance in areas of limited statehood with the following really thought-provoking argument: "Consequently, I depart from the notion that statehood is provided solely by the state. Instead, I suggest we think of statehood as a product which is produced by the state in association with other actors. There are examples abundant when state outsource – intentionally or not – the provision of basic functions to external actors. It is sufficient to think of who provides security in Afghanistan or Tajikistan, domestic authority in Kosovo or Bosnia, or public services in Mozambique or Burundi" (Zürcher, 2007: p. 11).

The telling slogan of Burris et al. (2008: p. 15) "The king is dead – long live the extended Royal Family" seems to neatly sum up these findings of an eroding state monopoly as a governance actor and the simultaneously growing importance of nonstate actors.

A second contrast we want to introduce is the contrast between 'traditional governing' and 'modern governance' as Werner Jann (2011) has put it (**Table 2**):

Table 2 'Traditional governing' and 'modern governance'

	'Traditional governing'	*'Modern governance'*
Citizen	● Voter ● Consumer ● Client	● Active citizen and coproducer of public goods ● Partner of social cooperation and political agreements (empowerment)
Society	● Addressees of governmental steering ● Pluralistic representation of interests ● Corporatistic bargaining systems	● Societal self-regulation ● Active civil society

The lesson to learn from this table is that the relationship between government and society is in both cases significantly different and that the role of citizens changes from a passive addressee of policies to an active partner in governance. Stressing the important role of societal self-regulation means to take notice of the regulatory power of corporate societal actors such as professions, business associations, trade unions and so forth; and referring to the significant part of an active civil society as a basic element of modern governance means to recognize the contribution of different types of NGOs to what is called modern governance. So government and governance can not only be distinguished in terms of state-centeredness, of modes of guidance and control, but also in terms of different sets of actors and different roles of citizens.

The third and here last lesson to learn is that governance is about coordination. One of the main characteristics of the governance concept is its basic assumption that the reality of modern statehood is marked by the plurality of actors: a variety of state actors – the state is not and has never been a monolithic body – nonstate actors – they may be genuine private actors or institutions of the third sector/civil society – and – last but not least – hybrid actors with roots in the private and public sector. To coordinate the actions of these various actors and their specific contributions to the public interest is therefore one of the most important tasks of the modern pluralist state.

The modes of coordination may vary considerably and reach from hierarchical regulation to regulated self-regulation or even to the adoption of private regulations by state laws (for more details see Schuppert, 2011b). To become aware of this wide variety of choices, it is useful to imagine them on a scale with hierarchy and self-regulation as its cornerstones (**Figure 1**):

In nearly every case, these modes of coordination are to a certain degree institutionalized and therefore supported by and embedded in a regulatory structure, which simultaneously enables and restricts cooperative action. All forms of a closer cooperation and partnerships like public–private partnerships (PPPs), privatizations, delegation by contract and so forth, have to follow rules, not necessarily state laws like company law. However, these rules must be a result of negotiation or agreed rules of procedure monitored by the parties involved. Governance as coordination is insofar unavoidably governance as rule making.

Governance in the World of Politics and Policies

Good Governance and Global Governance by Governance Indicators

On the international stage most successful branch of governance is 'good governance' (Nuscheler, 2009). There is what might be

Figure 1 Source: Börzel, T.A., Risse, T., 2005. Public–private partnership. Effective and legitimate tools of transnational governance? In: Grande, E., Pauli, L.W. (Eds.), Complex Sovereignty: Reconstitution Political Authority in the Twenty-First Century. University of Toronto Press, Toronto, pp. 195–216.

called a 'good governance promotion industry,' headed by the World Bank and influential think tanks like Freedom House and others, which function as transfer agents throughout the world. Their powerful instrument is the use of governance indicators; the best known are the World Wide Governance Indicators developed for the World Bank by Kaufmann et al. (2010). These indicators are rooted in the values of the Western world and oriented toward the relationship between good governance and economic performance (see also the recently published book by Acemoglu and Robinson, 2012). Considering the impressive career of the good governance concept and of good governance indicators, it seems quite appropriate when Davis, Kingsbury, and Merry call this mode of governance 'Global Governance by Indicators' (2012).

In contrast to the fact that political discussions are in general dominated by the good governance concept and that politicians of all countries and political colors like to think in rankings and benchmarks of good governance practices it is important to make clear that the primary goal of the governance approach is an analytical not a normative one. It is widely agreed upon that theory building in the field of governance has to start with an empirical analysis of the actual governance structures in a policy field or a given society and that the normative judgment in terms of the rule of law and theories of democracy has to follow as a second step. So the governance approach can be characterized as a two-step approach: analysis first, normative judgment on the basis of the empirical findings afterward. Otherwise, it would not be possible to look at governance in areas of limited statehood or to investigate the governance structures of the Hamas, Hezbollah, or of institutions and states at the borderline of organized crime (for governance as an analytical concept see especially Benz et al., 2007; Zürn, 2008; Schuppert, 2011a).

Governance by and as Communication

To govern means the ability to get things done. To achieve this, governments can use 'command and control' policies and negative and positive economic incentives. But that is not enough: more and more governments are dependent on persuading and motivating their citizens, a mode of governance, which Claus Offe (unpublished) has recently called 'ruling through signals': "The third family of policies is designed to affect courses of action through the sending of signals, defined as the dissemination of information which, if accepted as valid and incorporated into the beliefs of target actors, will modify their course of action. 'Signals are suggestions from the government. It encourages or recommends certain choices (…) and discourages others. With signals, in contrast to regulations, there is no enforcement and no compulsory compliance'" (Ringen: p. 8).

Stein Ringen, the by Claus Offe quoted scholar, discusses the phenomenon of 'ruling through signals' in a broader context; in a discussion paper with the nice title 'The Powerlessness of Powerful Government' he starts with the already mentioned two types of decisions, compulsory regulation and noncompulsory signals: "The orders contained in government decisions may be strong or weak. Decisions containing strong orders are called regulations: compliance is compulsory. Decisions containing weak orders I call signals; they are suggestions about behaviours or mindsets without compulsory compliance" (Ringen, unpublished paper: p. 6).

But then he comes up with a second important distinction, the distinction between 'power and authority.'

> Power explains a government's ability to get decisions made. But power is not what regulates its ability to get co-operation from its bureaucracies and compliance from its citizenry. For this, it does not help governments to be able to give orders, at least not very much; they need to be able to persuade. Persuasiveness is not contained in the weight of power; it depends on the strength of authority. Power is a necessary condition for a government to be able to rule but not a sufficient one. Once it is in power, its ability to rule depends on

> authority. Weak governments struggle for power. Powerful governments are beyond that but not be-yond struggling. They need to find the authority that can enable them to translate power into rule (p. 5).

But with this mode of governance, governments will be only successful, if they communicate their message, showing and practicing what we can call 'communicative leadership' (p. 11); this way of ruling seems to us the most promising mode of governance to meet the governance challenges ahead.

Three Examples for 'Governance at Work'

- Governance as crisis management: the case of financial governance

  The takeover of Merrill Lynch in March 2008 and the collapse of Lehmann Brothers 6 months later touched off a financial crisis that spread to many parts of the world. This caused severe governance problems, which forced the nation-states and the international community to look for innovative solutions. The main difficulty was that the problems were transnational whereas the financial and economic policies remained national: "Problems extend across borders more than before. At the same time, the jurisdictions for most economic policy remain national. Decisions national policymakers take create externalities for others. This suggests that coordination of policies across borders may help all countries. The EU attempted to coordinate policy in 2008–09 during the 'financial' part of the crisis, and it has put in place some new institutions meant to reduce the likelihood of future crises and to coordinate responses to crises when they occur" (Clark et al., 2013: p. 60).

  The national and European responses to the challenges of the global financial and economic crisis were quite remarkable. On the national level, the German legislature, for instance, created a new type of crisis reaction laws using a new and characteristic language: the German Bundestag passed three so-called 'Finanzmarktstabilisierungsgesetze' (Financial Market Stabilization Act) in 2008 and 2009 and in April 2009 a law for rescuing ailing banks, the so-called 'Rettungsübernahmegesetz' (Rescue Takeover Act). On the European level, the innovation was an organizational one; in September 2012 the European Stability Mechanism was established, an international financial institution situated in Luxembourg. This mechanism succeeded the European Financial Stability Facility and is at the very heart of the stabilization package. So the described governance innovations seem to support the well-known thesis of Joseph Schumpeter that every crisis owns a specific creative capacity.
- Transnational governance: the case of transnational rule making

  The governance area or governance realm that is referred to as transnational governance (Djelic and Sahlin-Andersson, 2006) is a space located somewhere beyond the reach of the nation-state and below the legal regime of international law and the authority of international organizations. In this space without clear-cut frontiers a need for transnational rules and transnational governance structures arises, a finding that Dieter Grimm (2003) puts as follows. "But beyond the nation state and the reach of international organizations modes of law making come into being, which cannot be influenced by states and international organizations. Global markets create regulations by themselves – independent of politics."

  Taking these findings as starting point, we can now try to describe the phenomenon of transnational governance in more detail.

  First, thinking in the category of new actors or new actor constellations, not only do we find a large number of them in the transnational realm but this space seems to be a perfect environment for the mushrooming of the type of actor that is characteristic of governance beyond the nation-state. We meet transnational standard setters such as 'standard-setting committees' in the field of accounting, transnational norm-building networks such as stewardships in different policy fields, transgovernmental networks as institutional backbones of a new world order (Slaughter, 2004), and – last but not least – actors such as rating agencies that are of the utmost importance for the governance of financial markets.

  Second, if we look for new modes of regulation, we have to explore a different world of rules compared to the legal system of nation-states. This world is characterized by the growing importance of standards created, for instance, by the International Standards Organization, codes of conduct of international corporations such as Shell or BP, and transnational contracts that are part of a new branch of governance labeled 'contract governance' (Riesenhuber and Möslein, 2009).

  Third, the most striking and – in terms of legitimacy and the rule of law – most challenging finding is the observable blurring of traditional borderlines, especially between public and private, formal and informal, and national and international. Examples of this erosion of borderlines in the transnational realm are so numerous that it might indeed be helpful to develop a 'theory of hybridity' (Trubek et al., 2005; Gillespie, 2009). Only one example shall be mentioned here: The erosion of the classic borderlines between binding and nonbinding norms through the process referred to as 'the hardening of soft law' (for more information see Schuppert, 2010).

  Fourth, it is more than obvious that new actor constellations, new modes of rule making, and the blurring of traditional borderlines raise a lot of questions in terms of legitimacy and accountability. The accountability problem is especially difficult to solve now that traditional chains of accountability become less omnipresent: how do we hold a network responsible, and how shall we deal with hybrid organizations? These questions are often discussed but rarely answered, and if progress is to be made in this difficult area, rethinking the concepts of accountability and legitimacy is needed.

  If we look back to the examples for transnational rule making, it is quite obvious that all these modes of rule making are so different in origin and character – from security standards to hybrid rule making by state-approved corporate governance codices – that they do not fit into

a passe-partout frame. Despite all these differences, some common features can, however, be found; following the observations of Stefan Oeter (2008) and Christian Tietje (2001, 2002), we can identify four peculiarities of transnational rule making:

- The first point is the deterritorialization of lawmaking. Although, the concept of law in the modern state is an etatistic and territorial one (Sassen, 2006), lawmaking under the conditions of globalization is a complex arrangement of territorial and deterritorialized law structures.
- The second characteristic feature is the blurring of the traditional borderline between binding and nonbinding norms. Lawmaking in a globalized world is a complex mix of nonbinding, semibinding, and legally binding norms, a mix of soft and hard law, and – to make it even more complicated – processes of hardening of soft law.
- The third aspect is an observable change from top-down lawmaking to a bottom-up system. While traditional lawmaking is a state-centered top-down process, modern transnational rule making is a process in which different actors and mechanisms are involved in network-style 'law production.'
- Above all, we witness a common trend to informality (Oeter, 2008). Informal rule making is not only a way to regulate when a legislative power is missing (for the role of soft law see Senden, 2004), it also seems to have many advantages in terms of flexibility and effectiveness, which means it has become increasingly popular.

- Governance as governance by partnerships

Policymaking is about choices – choosing the instruments that best suit a certain public policy (instrumental choice); choosing the 'right' organizational form or type of agency for implementing the policy in question (institutional choice); and – last but not least – choosing the appropriate regulatory regime, especially for the governance of partnerships (regulatory choice). To make the 'good choices' essential for effective public administration a certain amount of theoretical reflection is needed – as Donahue and Zeckhauser (2006) have pointed out with regard to 'collaborative governance': "Good governance requires choosing the right implementation model as well as the right ends. The richer the repertoire of alternative models, the more important is analytic work to guide the assignment of tasks. As government increasingly shares the collective-action stage with private actors, both for-profit and not-for-profit, addressing this assignment problem – who should do what? – becomes both more complex and more consequential."

To make these consequential choices in a sensible way, it is indispensable to be aware of the rich spectrum of choices as illustrated by Christoph Reichard (2006) in the following figure (**Figure 2**):

At the very heart of this choice, models are three sector-crossing institutional arrangements: contracting out, PPPs, and networks. As we come to networks later, it seems useful to say a few words about the differences and similarities between the first two modes of sector-crossing governance. At first, contracting out (this term is also used here as a synonym for 'functional privatization') and PPPs seem to be very similar: in both cases, the partners come from different sectors and their collaboration is governed by contracts. At a closer look, however, the differences are considerable, as the following table shows (**Table 3**).

As this table shows, to operate a PPP is a complex endeavor. The transaction costs are high. Choosing the appropriate partner causes information costs; facilitating control for the branch of public administration involved leads to high costs for comprehensive information and monitoring; and especially, the problem of developing a fair risk sharing requires high quality of governance.

Therefore, one of the best experts on PPPs in Germany – Detelf Budäus – has proposed to make a transparency report a necessary part of every complex PPP with an expected

Figure 2 Variety of organizational possibilities. Source: Reichard, C. (2006). New institutional arrangements of public service delivery. In: Reichard, C., Kupke, S. (Eds.), The governance of services of general interest between state, market and society. Wissenschaftsverlag, Berlin, pp 35–48.

Table 3 A comparison between contracting out arrangements and partnerships

Contacting out	*Partnerships*
Government and company (or consortium) are involved in a principal–agent relationship	Government and company (consortium) are involved in joint decision-making and production
Government defines the problem, specifies the solution, and selects a private company that can produce results in a cost-efficient way	Both parties are involved in joint processes early on in order to develop joint products that contribute to both their interests
Benefits of contracting out arrangements especially relate to efficiency (quicker and cheaper)	Benefits of partnership arrangements especially relate to increasing effectiveness (synergy and enrichment of output)
Keys to success are unambiguous definitions of goals, projects, rules of tendering, rules of selection, and rules of delivery	Keys to success are an interweaving of goals, establishing rules for ongoing interaction, developing rules, and tailor-made assignments concerning joint effort and production commitments
Based on the principles of project management, because there is a clear principle, clear goals, and well-defined project specifications	Based on the principles of process management because the joint goals, the art of financing, realization, and utilization remain subject to joint decision-making
Contractual transparency regarding rules of tendering, selection, delivery, and rules of inspection are crucial for a good relationship	Mutual trust is crucial for lasting relationships between partners who maintain their own interest, ways of working, accountability, and financing principles

peril of additional costs, consisting of the following elements (Budäus and Grüb, 2008: p. 48; **Figure 3**):

Only such a precaution could minimize the specific problems, which are normally raised by the fact that in every PPP project there is a 'point of no return,' as the following phase model illustrates (Budäus and Grüb, 2008: p. 47; **Figure 4**): PPPs can be found in nearly every field of policy – as the following four examples show (for details see Sack, 2006):

- Very popular are PPPs in the field of public transport. Not only in Germany but also in other European countries, highways, bridges and tunnels are built by private companies on their own expenses. In the PPP agreement, they are allowed to levy charges from the users. A famous example for a really complex PPP is the development of toll systems for trucks – called Toll Collect – in cooperation between the department of transport, Daimler Chrysler, German Telekom, and the French company Cofiroute.
- PPPs are used worldwide for building constructions, including schools, hospitals, jails or airports. In this field cost-explosions are a regularly made experience, a finding which supports the above mentioned instrument of a transparency report.
- A third example of the usefulness of PPP arrangements are the challenges of 'E-Government.' In this field, administrative agencies are often dependent on the specific know-how of private companies, an expertise which they can buy (contracting out) or integrate in an organizational PPP.

Figure 4 Phase model of PPPs at work.

Strength and Weaknesses of the Governance Concept

Beginning with the strength of the concepts I would like to make three points.

Governance as an Interdisciplinary Bridging Concept

That governance is a bridging concept seems to be widely accepted (van Kersbergen and van Waarden, 2004; Schuppert, 2006; Benz et al., 2007; Börzel and Risse, 2010). During the last 20 years, the governance paradigm has developed into a conceptual bridge enabling fruitful scientific exchange between political science, sociology, law, and history. At the same time, it enables scholars to talk about policies and politics beyond a narrow focus on the state.

However, following this metaphor of governance as a bridging concept implies that a coherent and comprehensive governance theory cannot exist on its own. If the pillars of the bridge are rooted in different disciplines – the recently published SAGE Handbook of Governance (2011) mentions 11 different approaches as 'theories of governance'– a 'governance theory' is by its very nature a multidisciplinary endeavor with all the weaknesses and advantages of a multifaceted scientific approach that seeks to explain the dynamics of politics and policies.

Governance as a Mirror of Changes in Statehood

There is – as it seems – a broad consensus in the governance community that governance and changes of statehood belong together and that changes in governance reflect changes of statehood. As a witness of this consensus, we want to quote some sentences, which can be found in the concluding remarks of the introductory article of Mark Bevier in the SAGE Handbook of Governance:

> The term 'governance' has risen to prominence in the last 30 years as a way of describing and explaining changes in our world. […] Typically, the new governance refers to changes in the nature and role of the state since the last quarter of the twentieth century. The state has become increasingly dependent on organizations in civil society and more constrained by international linkages. On the one hand, the public sector in many states has shifted away from bureaucratic hierarchy and toward markets and networks; governance thus captures the ways in which patterns of rule operate in and through groups within the voluntary and private sector. On the other hand, states have become increasingly embroiled with transnational and international settings as a result of the internationalization of industrial and financial transactions, the rise of regional blocks, and concerns over problems such as terrorism and the environment; governance thus captures the formal and informal ways in which states have attempted to respond to the changing global order.
>
> Bevir, 2011: p. 15.

Governance as an Analytical Tool for Studying the Institutional Architecture of Modern Statehood

A very good example of the analytical capacity of the governance concept is the contribution to explain the institutional architecture of modern statehood from the network governance research (Börzel, 1998; Kenis et al., 2008). In the famous book 'A New World Order,' Anne-Marie Slaughter (2004) has given 'governance by government networks' a very prominent place. She illustrates how this mode of

governance works by looking at the 'networking of finance ministers and top bankers' (p. 38):

> Networking among some regulators, such as central bankers, securities commissioners, and insurance supervisors, has become so established that they now have their own international organizations – the Basel Committee, IOSCO Commissioners and IAIS, among others. These organizations are transgovernmental networks that have become sufficiently formalized to warrant the title of association or organization and that have a staff and regular meetings. But they are not 'inter-state' organizations; they are not formed by treaty or even executive agreement; they have no place on the landscape of the international legal system.

The main tasks of such networks are – as Anne-Marie Slaughter points out – the following:

- exchanging information,
- coordinating policy,
- cooperating on enforcement issues,
- collecting and distilling best practices,
- exporting particular regulatory forms,
- bolstering their members in domestic bureaucratic politics, and
- transmitting information about their members' reputation.

If we look at this very illuminating list, it is obvious that networks cannot function without a very intensive communication; they practice what can be called 'governance by and as communication.' The best proof for that is the short answer of A.M. Slaughter to the question what networks are doing: 'Their members talk a lot' (p. 51).

But of course there is also some criticism of the governance concept:

The most popular criticism is the reproach that the governance concept neglects the dimensions of power and politics. Claus Offe, for instance, argues that governance has – in contrast to steering – no subject, only structures: "Something happens but no one has done it and no one would be responsible." (Offe, 2008: p. 61) Similar are the critical remarks of Edgar Grande: What does steering by governance structure mean, who is the actor behind governance institutions and governance arrangements and, does it really make sense to speak of institutional steering by governance structures (Regelungsstrukturen)? The answer is yes, it makes sense to talk about institutional steering (Schuppert, 2012). Politics is not only as mentioned above about institutional choices, but also about designing and creating new institutions or reforming traditional ones. All the political controversies of the last 20 years have been arguments about 'getting the institutions right'; that is true for the reform of the school system, the health care structure, the reform of financial federalism, the rescue of the Euro, labor market policies, and so forth: designing and creating institutions is making politics and exercising power (Olsen, 2010).

To sum it up, we would argue that the advantages of the governance concept outweigh its weaknesses in a very convincing manner.

Government Statistics

M Straf, National Research Council, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Government statistics are essential for a democratic government and they serve to advance businesses and the well-being of its citizens. Statistical agencies provide accurate, timely, and credible information, which informs current and future policies. Respect and trust of data providers are fostered by maintaining confidentiality of their information. Government statistics are collected through censuses and surveys and from administrative records and other sources. Defining practices of an effective statistical agency begin with a clear, well-accepted mission and a strong standing of independence. Today, statistical agencies are challenged to keep up with technological change and new sources of data in a rapidly changing world with a global economy.

Introduction

Government statistics are vital to advance the economic well-being and quality of life of a nation's citizens. Without such statistics, policy making would be less effective, economic markets would be less informed, and the countless decisions of private businesses and individuals would allocate economic and other resources less efficiently. But more, government statistics are vital to a democracy, as the information they convey provides the means by which citizens can hold their government accountable.

This article provides a general review of government statistics largely in the context of the USA, but it also addresses broader issues relevant to other countries. The focus is on the national government and, therefore, mostly on national statistics, but much is also relevant to governments at subnational levels, which also produce statistics.

The article begins with the purposes of government statistics and the rationale for why governments produce them. Next it takes up the principles by which the statistics should be produced to serve these purposes effectively; this is followed by descriptions of various types of data collection and of how the responsibilities for collection, analysis, and reporting of statistics are organized among statistical agencies. Effective practices of these agencies are identified. The article concludes with a discussion of some challenges faced by statistical agencies.

Statistics from government sources are referred to in many articles in this Encyclopedia (*see* Censuses: History and Methods; Censuses, Population: Comparative International Aspects; Census: Current Approaches and Methods; Census Microdata; Panel Surveys: Uses and Applications; Sample Surveys: Cognitive Aspects of Survey Design; Large-Scale Social Surveys, Analysis of; Data Bases and Statistical Systems: Applied Social Research; Data Bases and Statistical Systems: Demography; Data Bases and Statistical Systems: Economics (General)).

What Are Government Statistics?

'Government statistics' means factual information that is reported upon for statistical purposes by a unit of government. Some countries also use the term 'official statistics.' In this article, 'statistics' and 'data' are used interchangeably to mean factual information, and the terms are not restricted to quantitative information. Usually, the unit or agency of government that issues the statistics has collected or compiled the data to produce them. In most cases, the agency is a distinct entity of government entrusted with reporting the statistics. In some cases, the agency may analyze its data to provide more information about the statistics in its reports, especially information that makes the statistics more relevant to public policy concerns. For the agency to be effective, the focus of any analysis must be on ways to improve the relevance and accuracy of data for their use in public policy analysis and decision making and to explain what the data mean or imply, but not to advocate any particular policy.

The *sine qua non* of the definition of government statistics is that they are collected and reported upon only for *statistical purposes*:

> 'Statistical purposes include description, evaluation, analysis, inference, and research. Statistical purposes relate to descriptions of groups and exclude any interest in or identification of an individual person or economic unit. For these purposes, a statistical agency may collect data directly from providers, or it may obtain data from other sources, but it does not use these data for administrative, regulatory, or law enforcement purposes. The data are used solely to describe and analyze statistical patterns, trends, and relationships involving groups of individuals or other units.
>
> NRC, 2013b, p. 10

Why Do Governments Produce National Statistics?

A government provides statistics to inform its citizens, satisfying an essential requirement of a democracy (see, e.g., United Nations Statistical Commission, 1994). The government, however, is most often a primary user of the statistics it produces. The statistics are used in the formulation of, and decision making on, public policies, as well as in their implementation and evaluation. Information from statistics, for example, is used to inform economic markets and monetary policy; to determine the effects of proposed policy changes; to adjust taxes and benefits, as well as private contracts; to allocate government funds among state or regional

governmental entities; to inform decision making at these levels; and to inform private sector investment decisions and individual decision making.

In most cases, a government collects and reports the statistics itself, either directly or through the services of a private organization. In a few cases, the private sector satisfies the demand for national statistics. Examples are the Conference Board's compilation of US leading economic indicators, abortion statistics for many countries compiled by the Alan Guttmacher Institute, and many private market-research surveys and reports of economic forecasting firms. But even when the private sector can do so, there are reasons for a government to collect the statistics. Alternative sources may not exist. Timeliness may be a critical factor. And statistics collected by government agencies are often deemed to be of greater quality.

A more compelling reason may be trust and credibility. Potential subjects of government data collection may be more willing to volunteer their time and effort and divulge confidential personal or proprietary information for a government survey rather than for a private one, in part because of legal protections of confidentiality. And the public and other important users may find data collected by the government to be more credible.

A fundamental reason, however, for a government to collect data has to do with the very nature of data. If a commodity can be consumed by many and consumption by one does not reduce the consumption of others, then the commodity is a 'public good.' Data are manifestly public goods: use of data by one party in no way diminishes their usefulness to other parties. Individuals benefit from a public good but, unless each individual is charged for the consumption of the good, they are unlikely to pay for them voluntarily. Consequently, the goods may not be produced, unless the government intervenes. In the case of data, the government may intervene directly by collecting the data, or it may intervene indirectly, for example, by defining rights for a license or copyright to provide the means for the private sector to charge for the value added in producing secondary data (data used or prepared for uses other than the purpose for which they were collected). For these reasons, a government typically provides primary data (data collected for a specific purpose) and the information infrastructure. The private sector typically provides secondary data and may build on the infrastructure.

Principles of Government Statistics

A report of the US National Research Council of the US National Academy of Sciences, National Academy of Engineering, and Institute of Medicine (NRC, 2013b) defines a 'statistical agency' as a unit of government whose principal function is the compilation and analysis of data, and the dissemination of information for statistical purposes. The unit is recognized generally as a distinct entity, which may be located in a cabinet department or independent agency. The mission of a distinct entity or agency of government that issues government statistics may or may not be solely statistical.

Statistical agencies are established to be a credible source of accurate, timely, and relevant statistics in one or more subject areas. Accuracy requires proper concern for consistency in spatial and temporal dimensions, as well as statistical measures of error. Timeliness requires concern for the frequency of issuing data, as well as disseminating data to users when they need them. Relevance requires concern for anticipating future data needs, as well as meeting current ones. And credibility requires concern for the reality and appearance of impartiality, as well as the reality and appearance of independence from control for partisan political purposes. It is essential to the mission of statistical agencies to work to ensure the goals of accuracy, timeliness, relevance, and credibility of statistical information.

The US National Research Council report identifies four principles for a statistical agency. The first is that the agency is in a position "to provide objective, accurate, and timely information that is relevant to issues of public policy" (NRC, 2013b, p. 12). This principle requires the agency to be knowledgeable about public policy issues and be able to provide objective information that is relevant to the needs of formulating, implementing, and evaluating public policies. The second is that the agency has credibility with those who use its data and information. To develop that relationship, an agency must strive to maintain credibility for itself and for its data. In particular, the agency must be perceived to be free of political interference and policy advocacy. Other aspects that contribute to credibility are a commitment to quality and professional standards and openness about all aspects of the data, especially the quality of the data.

The third principle is that the agency has a relationship of mutual respect and trust with respondents who provide data, and with all data subjects whose information it obtains. Statistical agencies rely in large part on information supplied by individuals and organizations outside the federal government, such as state and local governments, businesses, and other organizations. Some of this information is required by law, such as employers' wage reports, and some of it is compiled from records of government programs. But much of it is obtained through the voluntary cooperation of respondents to surveys. Even when the response to a survey is required by law, cooperation by respondents promotes accuracy, which, in turn, promotes the credibility of the agency's data. In encouraging cooperation, it is important to statistical agencies that respondents perceive that the information they are being asked for is important; that it is being collected in an impartial, professional manner; that their privacy and autonomy are respected; and that their personal or proprietary information will remain confidential.

When statistical agencies pledge to keep respondents' information confidential, it means that the information will be used only for statistical purposes and that, in particular, it will not be used for any administrative, regulatory, or enforcement purpose regarding the individual (*see* Confidentiality and Statistical Disclosure Limitations).

Statistical agencies go to great lengths to maintain the confidentiality of individual responses (see NRC, 1993, 2000). In the USA, some agencies, such as the US Census Bureau, long had legislation to protect confidentiality, and some, such as the US Bureau of Labor Statistics, have had a history of successful reliance on executive order, custom, and case law. A federal law, the Confidential Information Protection and Statistical Efficiency Act of 2002 (CIPSEA), established a uniform set of safeguards to protect the confidentiality of individually

identifiable information acquired from the public for statistical purposes by any agency of the US government. With this protection, CIPSEA also authorizes the sharing of business data among the Bureau of Economic Analysis (BEA), the Bureau of Labor Statistics (BLS), and the Census Bureau (Census), to achieve efficiencies.

In Europe, the 1995 European Community Directive on Data Protection governs the transfer of individually identified or identifiable data. The European Commission has proposed a comprehensive reform to modernize and extend this Directive (European Commission, 2012), which was supported by the European Parliament (European Commission, 2014).

The respect and trust of data providers are also essential for statistical agencies to achieve credibility for their data. Protecting the confidentiality of individual responses engenders trust.

Respect for data providers also means valuing their time and effort to respond, in particular, designing data collection so that it is not unduly burdensome and valuing their responses so that they are put to important uses. It is important too that respondents perceive that the agency collecting their information is trustworthy and credible, in particular, that the information will not be used for a particular partisan interest. A statistical agency must be perceived, by its data providers as well as its data users, to be working in the national interest.

The fourth principle is that a statistical agency be independent from political and other undue external influence in developing, producing, and disseminating statistics. A statistical agency should encourage external input on its programs, of course. By an 'undue external influence' the National Research Council report means that which seeks to undermine the agency's impartiality and professional judgment. Independence from such influences – in appearance as well as in reality – is essential for credibility with data users and the public.

How Are Government Statistics Collected and Reported?

Statistical agencies collect data through censuses, surveys, and compilations from administrative records and other sources. Some agencies use nontraditional sources, such as private vendors for expenditure data, and some are exploring new sources, such as Internet websites, for example, price data for online purchases, and transaction data, for example, purchase data scanned in retail stores. The vast amount of electronic data available presents challenges to extract useful information and raises questions of quality and representativeness.

Many countries conduct a census of their population. In the UK and USA, one is conducted every 10 years; in Canada, every 5 years. To provide more timely data than which were previously collected only every decade in the census, the US Census Bureau conducts the American Community Survey of approximately 250 000 addresses monthly.

Other examples of US censuses are the quinquennial census of agriculture, which covers agricultural production on farms that are defined as places from which $1000 or more of agricultural products were produced and sold in the census year; the quinquennial economic census, which covers the economic activity of nonfarm establishments; and the quinquennial census of governments, which covers employment and finances of state and local governments.

Examples of surveys in the USA include the Current Population Survey, from which monthly employment and unemployment data are derived; the Consumer Expenditure Survey, from which data on expenditure patterns are used periodically to adjust the weights of goods and services in producing the Consumer Price Index; and the National Health Interview Survey, which provides annual estimates of health conditions and use of healthcare services. Data in government surveys may be collected by field staff of an agency (e.g., the Census Bureau conducts the Survey of Income and Program Participation with its field staff); by state or local governments under a cooperative program (the Current Employment Statistics program of the Bureau of Labor Statistics is a monthly survey, based on payroll records of business establishments, conducted by state employment security agencies); or by another federal agency (the Census Bureau conducts the Current Population Survey and the Consumer Expenditure Survey for the Bureau of Labor Statistics and the National Health Interview Survey for the National Center for Health Statistics). In addition, private organizations may collect data for a government agency under a contract or grant (the University of Michigan conducts the Health and Retirement Study under a grant from the National Institute on Aging).

Many of these surveys have counterparts in other countries: for example, the Labour Force Survey of the Office of National Statistics in the UK and the French Labor Force Survey of the National Institute for Statistics and Economic Studies in France.

The units of observation in surveys may be individuals, households, families, schools, establishments, or other economic units. Surveys may be cross sectional to provide an estimate at a point or interval of time, or they may be longitudinal in design in that they follow the same units of observation over time. Longitudinal surveys can provide information on changes in a unit over time: for example, transitions of families in an out-of-poverty status from the Survey of Income and Program Participation (*see* Longitudinal Data: Event–History Analysis in Discrete Time; Panel Surveys: Uses and Applications). Some surveys, such as the American Housing Survey, however, may also employ a longitudinal component in their design to reduce error or increase efficiency.

Statistical agencies also compile information from administrative records. For example, vital statistics are compiled by the National Center for Health Statistics from state agencies, and administrative records are the source of basic statistics for very small firms in the quinquennial economic census, thus reducing or eliminating the need to send these firms census questionnaires.

Statistical agencies may be dependent on the censuses and surveys of other agencies as well as their own data collection in order to produce national indicators. The Bureau of Economic Analysis relies heavily on economic statistics from other sources in compiling the national income and product accounts. And most agencies rely on the Census Bureau to produce the population denominators for reported rates.

Since the US statistical system is so decentralized, important information on a population of interest, such as children or the elderly, is often collected by many agencies and in different ways that may make relating the data difficult, if not

impossible. Sometimes, agencies collaborate to fill important information gaps. Two examples are key indicators of well-being for older Americans (Federal Interagency Forum on Aging-Related Statistics, 2012) and for children (Federal Interagency Forum on Child and Family Statistics, 2013).

Whatever the source of data, one of the most important activities of a statistical agency is measuring, controlling, and reporting upon error. Statistical agencies have been preeminent in the development of survey designs to reduce sampling error. And many require, as a standard for some forms of publication, that statistical errors be reported. The agencies too are concerned about measurement and other forms of nonsampling errors, and employ various means to study them, including reinterview studies, record checks, multiple indicators, and cognitive studies, which focus on how errors arise in the process of answering questions. Three statistical agencies, the Census Bureau, the Bureau of Labor Statistics, and the National Center for Health Statistics, have cognitive laboratories to evaluate questionnaires and conduct other research to better understand and reduce error (*see* Sample Surveys: Cognitive Aspects of Survey Design; Questionnaires: Cognitive Approaches).

How Are Government Statistics Organized?

Government statistical activities may be centralized into a single agency or not. The organization in the USA, which is described first, is highly decentralized with activities dispersed among many agencies. Some of the trade-offs between centralized and decentralized systems are described at the end of this section.

The US Statistical System

The USA has a highly decentralized statistical system, with over 100 agencies having direct funding of over $500 000 per year for statistical activities. Only some of these agencies are statistical agencies (US Office of Management and Budget, 2014b).

The highly decentralized statistical system in the USA arose historically because, as new subject matter areas emerged as a national priority, new statistical agencies were created to meet the needs for new data. Little attention was paid to the relevant data-collection activities of other agencies. Efforts at collaboration have met with some successes, such as the interagency forums on aging-related statistics and on child and family statistics, but achieving systemic collaboration has proved more difficult. Attempts to achieve collaboration through centralization, or at least a major consolidation, have run into stakeholders with a special interest in retaining strong, relatively independent agencies within a particular department of government (see Norwood, 1995).

Responsibility for coordinating the myriad statistical activities of the US government rests with a small unit in the Office of Management and Budget, the Statistical and Science Policy Office in the Office of Information and Regulatory Affairs. Authorization of that responsibility derives from legislation originally concerned with paperwork reduction. Despite its small size, however, the Statistical and Science Policy Office has brought statistical agencies together to address many matters of common concern.

The 1995 reauthorization of the Paperwork Reduction Act codified an Interagency Council on Statistical Policy, formalizing an arrangement whereby the heads of the principal statistical agencies meet regularly together with the US Chief Statistician, who heads the OMB Statistical and Science Policy Office. The Council comprises 13 principal statistical agencies: the Bureau of Economic Analysis and the Bureau of the Census in the Department of Commerce; the Bureau of Justice Statistics in the Department of Justice; the Bureau of Labor Statistics in the Department of Labor; the Bureau of Transportation Statistics in the Department of Transportation; the Economic Research Service and the National Agricultural Statistics Service in the Department of Agriculture; the Energy Information Administration in the Department of Energy; the National Center for Education Statistics in the Department of Education; the National Center for Health Statistics in the Department of Health and Human Services; the Statistics of Income Division of the Internal Revenue Service in the Department of the Treasury; the Office of Research, Evaluation and Statistics in the Social Security Administration; and the National Center for Science and Engineering Statistics in the National Science Foundation.

The Interagency Council, the Federal Committee on Statistical Methodology and other interagency committees it convenes, and the Committee on National Statistics of the US National Research Council (National Academy of Sciences, National Academy of Engineering, and Institute of Medicine) have addressed many methodological and other issues that cut across the interests of most statistical agencies. These include issues of poverty measurement, definitions of race and ethnicity and of metropolitan areas, and confidentiality of government statistics. The Statistical and Science Policy Office is also concerned with international comparability of statistics, and it represents the USA at the United Nations Statistical Commission and other international organizations. Moreover, the Statistical and Science Policy Office has striven to extend the protection of confidential data in ways that would allow statistical agencies to share needed information under that protection.

The Statistical and Science Policy Office is the only unit of government charged to be concerned with the government statistical system as a whole. It conducts an annual review of all major statistical programs and publishes a special analysis of funds proposed for statistical activities in the President's budget (US Office of Management and Budget, 2014a).

Centralized versus Decentralized Systems

Most large countries of the world have centralized most or all of their statistical activities into a single agency with broad authority for collecting and compiling government statistics. Coordination of the different activities occurs within the agency itself. Examples are Statistics Canada, the statistical agency of Canada, and the Australian Bureau of Statistics.

A central statistical agency is usually seen to be more efficient in resource allocation; in reaping the benefits of scale; in sharing information across different subject matter areas in order to enhance data and to avoid duplicating activities; in coordinating data activities, such as developing a single longitudinal survey of youth that serves the purposes of both health and education policy makers; and in arranging for the effective

use of administrative data. Advantages of a decentralized system are that priorities for budget, relevance, and timeliness, and the urgency to meet needs for new data are set within the department with the most concern for the information and with policies that are most affected by it, and that different perspectives and ways of conducting statistical activities can bring strength to the system as a whole.

Practices of Effective Statistical Agencies

The operation of an effective statistical agency begins, first, with a clearly defined and well-accepted mission and, second, with necessary authority to protect independence. With these prerequisites, a number of practices contribute to the agency's effectiveness. According to the National Research Council (2013b) report on principles and practices for a statistical agency, these include continual improvement of and development of more useful data; openness about its data; wide dissemination of data; cooperation with data users; fair treatment of data providers, in particular respecting their privacy and autonomy and protecting the confidentiality of personal information they provide; commitment to quality and professional standards, including through a highly professional staff; an active research program; a strong program of evaluation; and coordination and collaboration with other statistical agencies. Effective statistical agencies also engage in the analysis and interpretation of their data and in advancing their effective use.

Mission

An agency's mission should include responsibility for assessing and meeting needs for information in its purview, determining the sources of the data and the measurement and collection methods, and ensuring that its data are available to the public. An agency mission statement often goes beyond its charge in legislation. In particular, it should articulate the principles that will govern all of its work. The mission should be well accepted externally by the agency's department and others who oversee the agency, and especially by data users. It should also be well accepted internally, so that all agency employees understand how their work furthers the mission.

Independence

A strong and widely acknowledged standing of independence from undue external influences is necessary for a statistical agency to have the credibility to carry out its mission effectively. In particular, the agency must be independent of other parts of its department engaged in policy making, enforcement, regulatory, or administrative activities. It must be impartial and avoid even the appearance that its data might be manipulated for political purposes, or that information on an individual might be used for enforcement, regulatory, or administrative purposes.

Forms of independence differ among statistical agencies. Some of the other characteristics of independence include authority to decide the scope, content, frequency, and manner of data collected, compiled, or reported; to select and promote professional staff; to release statistical information without prior clearance and with a clear separation from policy interpretations by others; to represent the agency's statistical program before legislatures and the public; and to establish and follow predetermined schedules for the release of important economic and other indicators.

Continually Developing More Useful Data

In order to make their data more useful and to meet changing public policy needs, statistical agencies must continually look to develop data systems that can serve broader purposes. Integrating data from surveys conducted by different agencies or integrating data from surveys with data from administrative records, such as tax or social welfare program records, are ways to achieve this goal. When separate data sets are collected and analyzed in such a way that they may be used together, the value of each may be greatly enhanced. Data sharing and statistical uses of administrative records, with appropriate safeguards for confidentiality, also make a statistical agency more efficient as well as more effective.

Openness

An effective statistical agency operates in a completely open manner. Openness requires providing full documentation of the data with acknowledgment of any uncertainty, a description of the methods used and assumptions made, and measures or other descriptions of error, for both sampling and nonsampling error. When a mistake occurs, the agency should acknowledge it promptly and publicly. For a correction to an important indicator, the agency should strive to inform as many current and potential users as possible.

Dissemination of Data

An effective statistical agency seeks the widest possible dissemination of its data through a variety of means, including public-use data files and the agency's website, and has policies to guide what data to archive and how.

Cooperation with Data Users

An effective statistical agency consults with a broad range of users of its data in order to make its products more useful. It seeks advice on data concepts, methods, and products in a variety of formal and informal ways, from data users as well as subject-matter and other experts. It endeavors to meet the needs for access to data while safeguarding the confidentiality of individual responses. And it strives to provide easy and equal access to all potential users.

Fair Treatment of Data Providers

A statistical agency must maintain a relationship of respect and trust with its data providers. It does so through fair information practices, which include protecting the confidentiality of data identified with an individual, whether the data are collected directly or obtained from administrative record sources; informing respondents of the purposes of data collection and the expected uses of the information; informing those asked

to report whether their participation is voluntary or mandatory, and using appropriate informed consent procedures for voluntary data collections; minimizing the contribution of time and effort asked of respondents, which may be achieved in seeking the advice of respondents in the planning and design of data collection; and respecting the willingness of respondents to contribute to society by representing accurately the information they provide, and by making it available for important uses.

Research

An active research program is integral to the activities of an effective statistical agency. Research may be conducted on the substantive issues for which the data were compiled, especially concepts and definitions; methods of measurement, collection, analysis, and dissemination; and topics to improve the utility of the agency's data in policy analysis and decision making.

Quality and Professional Standards

An effective statistical agency is committed to the highest standards of quality work and professional practice and ethics, in statistics and other relevant professions. A statistical agency should recruit, develop, and retain professional staff committed to high standards of quality, in particular through strong and continuous relationships with appropriate professional organizations in statistics and relevant subject-matter areas.

Evaluation

Statistical agencies must continually evaluate their statistical programs for accuracy, relevance, timeliness, efficiency, and cost-effectiveness. Regular formal reviews should consider ways to reduce duplication through effective uses of administrative records and other data sources and to adjust priorities to meet current policy needs. Evaluations should include both internal reviews by staff and external reviews by independent groups.

Coordination and Collaboration

In the US context, an effective statistical agency continually seeks opportunities to cooperate with other statistical agencies to enhance the value of its own and other agencies' information. Statistical agencies cooperate, not only with each other, but also with state and local statistical agencies in the provision of data for subnational areas. They cooperate, too, with foreign and international statistical agencies to exchange information, on both data and methods, and to develop common classifications and procedures to promote international comparability of information.

Integrating data collected or compiled by different statistical agencies invariably requires much coordination and cooperation among the agencies, each of which have different missions. But the rewards are data more relevant to policy concerns, and a stronger statistical system as a whole. For these reasons, statistical agencies must cooperate as partners with one another, not only on the development of data, but also on the entire panoply of statistical activities, including definitions, concepts, measurement methods, analytical tools, professional standards, dissemination modes, ways to advance the effective use of their data, and means to protect the confidentiality of responses.

Analysis and Interpretation

Agencies can make their data more relevant to public policy concerns by analyzing and interpreting the data. Care must be exercised, however, that analyses are not perceived as policy advocacy. Analyses of data also reveal where improvements in data are needed.

Advancing Effective Use of Statistics

Statistical agencies should also advance the uses of their data through making them easily accessible to users in convenient forms, involving data users in planning data collection and dissemination, and providing full documentation and other forms of technical support to users.

Challenges Faced by Statistical Agencies

We live in a rapidly changing, increasingly interdependent world with a global economy. Many countries face profound demographic changes. Primarily fueled by technological advances, widespread changes are occurring in society, the environment, and international relationships. Governments struggle to keep up with the changes. They are concerned with the need for new property rights, laws governing new markets, new forms of businesses, and investments in new technology for education. They are concerned too about mitigating human error in transportation, communications, healthcare, and other complex, critical systems and protecting the security of these systems; avoiding harmful effects on the environment and sources of food; and guarding against the loss of individual privacy. And governments are also concerned with disparities in economic growth and the distribution of income and wealth, to which disparities in access to technology may contribute, since these disparities could increase tensions among social groups and nations.

An efficient, flexible, and modern information system is essential for a government to address these and other concerns. The greatest challenge facing any statistical agency is for it to keep up with the times. "Public policy analysis often cannot wait until new surveys are undertaken, but must rely on knowledge drawn from the existing statistical database" (Cook, 2000). Those in charge of government statistics must anticipate and prepare for future needs.

Other challenges that statistical agencies face are the decline in survey response rates in the USA and other developed countries (NRC, 2013a), making greater use of administrative records for statistical purposes (OMB, 2014a), and understanding when nontraditional methods, such as nonprobability sampling, may have utility (Baker et al., 2013).

Technology, which has induced so many rapid changes, itself can give statistical agencies the means to respond to these challenges. The agencies must not only incorporate new

technology into collecting, processing, analyzing, and disseminating government statistics, but they must also prepare for the plethora of new data in digital form.

Advances in information technology are also making it more and more difficult to protect confidentiality, and the widespread use of data analytics and experiments on 'big data' that are easily captured have changed the meaning of privacy in our digital age. If a statistical agency is to respect its data providers by putting their information to use in the best way to benefit society, stronger ways to protect confidentiality must be sought. Statistical agencies should lead in confidentiality research, including research on data encryption and in fostering legal and administrative means to protect confidentiality (*see* Confidentiality and Statistical Disclosure Limitations).

Conclusion

Government statistics are essential for a government to function effectively and to advance businesses and the well-being of its citizens. The nature of data as a public good provides an economic argument for a government to collect statistics, but there are many other reasons for it to do so. One is to assure accurate, timely, and credible information that its citizens may use to hold their government accountable on any issue. A statistical agency must be able to provide information relevant to current and future policy issues, and to establish credibility for itself and its data, in particular with a strong standing of independence. Finally, the agency must be respected and trusted by respondents who provide it with data and with all data subjects whose information it obtains. That respect and trust can be fostered by protecting the confidentiality of individually identifiable information and by putting the information it obtains to use in the best ways to benefit society, including research.

More information on the principles and practices of statistical agencies can be found in the National Research Council report (NRC, 2013b) and on the organization of US statistical agencies in Norwood (1995). Statistics for over 200 countries and areas of the world are compiled by the United Nations Statistics Division (2011). Links to the websites of statistical agencies in the USA are available at www.fedstats.gov.

Governmentality

Marc Abélès, Ecole des Hautes Etudes en Sciences Sociales, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The introduction of the concept of governmentality at the end of the twentieth century has given a new impulse to the study of contemporary political power and institutions in a global context. It can be seen as the result of two converging intellectual movements. One emerged from the critique of the ethnocentric category of the state by the political anthropologists; the other comes from the philosophy, more precisely from the genealogy of neoliberalism proposed by Michel Foucault who imposed this concept in the field of social sciences.

The introduction of the concept of governmentality at the end of the twentieth century has given a new impulse to the study of political power and its institutions. It can be seen as the result of two converging intellectual movements. One is to be found in the anthropological literature, specifically in the critique of the ethnocentric category of the state; the other comes from the philosophy, more precisely from the genealogy, of neoliberalism proposed by Michel Foucault in the field of social sciences.

Stress has often been laid on the contrast between traditional societies in which the political sphere is embedded and the modern world in which the autonomy of politics is manifested in the organization of states and their many institutions. For a long time, anthropology was confined to exotic societies, and the counterpart to this preference for far off places was the creation of boundaries between universes perceived as having different ontological properties. Two contrastive approaches were thus adopted: one appropriate to an understanding in which it is difficult to separate the political from other aspects of reality, and the other applicable to contemporary societies, where politics as an institution is clearly circumscribed. This implicitly set limits on the work of anthropologists and gave sociologists and political scientists a monopoly on research on modernity. The division of labor has certainly had some positive effects, since it has enabled the different disciplines to delve very deeply into the areas assigned to them.

At the same time, the boundary that has been created could not resist for long the curiosity that anthropologists felt for their own societies, which eventually led them to expand their areas of investigation. It is true that the modern state appears to be very remote from the archaic structures and faltering institutions that once attracted anthropologists. With its complex civil service, dense bureaucratic fabric and deployment of hierarchies, the functioning of the state in western societies bears the little resemblance to the much more diffuse operation of politics in the exotic world. There is a real disparity of scale between contemporary state formations and the systems that the anthropologists have previously described such as segmentary societies or chiefdoms. But it has not prevented the development of an anthropology of the state focused on the everyday practices of the bureaucracy with its official procedures and routines (Sharma and Gupta, 2006). A number of ethnographic studies have offered relevant analyses of the functioning of administrative and repressive state apparatuses and the way in which the ideological state apparatuses realize "the interpellation of 'individuals' as subjects" (Althusser, 2006: p. 108).

One of the main contributions of anthropologists to the study of politics has been to demonstrate how the state's rise as a political system was contingent on a specific historical context. Anthropologists have thus suggested that the state is susceptible to eventual disappearance and replacement by other political constructions (Abélès, 2005). From a comparative perspective, they have clearly shown that the state is only one form of government among many others. In the era of globalization, with the emergence of new transnational political forms, the Hegelian preeminence of the state has been challenged, and one aim of political anthropology is to offer a better understanding of this great transformation. As a consequence of globalization, in a world where economic processes subvert frontiers, state action is more and more dependent on economic constraints (Appadurai, 1996; Strange, 1996; Trouillot, 2003) and the rules of financial markets. We simultaneously find the limits of the concept of sovereignty and the emergence of 'multilayered governance' (Rosenau and Czempiel, 1992) that seems closely connected to the rise of the information society (Castells, 1996). Even critical theories of contemporary capitalism have profoundly reworked political concepts, to which the post-Marxist vision of Hardt and Negri (2000) testifies, returning to categories of flow and deterritorialization (Deleuze and Guattari, 1980) in order to comprehend transformations in the mode of production that characterizes the contemporary world. These critics substitute the antagonism between empire and multitude for the Marxist class struggle, whereas the social movements that rise against the surveillance society have neither common enemies nor common languages.

The focus in writings about global politics differs as to the institutions that govern society. According to their orientation, authors emphasize either the emergence of new political forms or the continuity of traditional structures. But the dominant point of view is a top-down vision, one that accents the rationality or the irrationality of centralized political processes in the context of globalization. This vision, however, is partial in both senses of the term: it does not take into account the main aspects of current changes at the global level and is indifferent to new representations of political action in contemporary societies. The time has come for reconsidering the statist conception that oriented most of the political studies and that

does not afford a relevant framework in order to understand globalization and its consequences.

Long time ago, in his Preface to *African Political Systems*, Radcliffe-Brown (1940) considered that the state, as a concept, was an epistemological obstacle. From an anthropological perspective, the focal issue is that of governing. Here, one can point out the convergence between political anthropology and the political theory articulated by Michel Foucault for whom reference to the state was much more a theoretical fetish than an efficient instrument used to better understand the operation of what he termed 'governmentality.'

As Foucault wrote: "The analysis in terms of power must not postulate as given the sovereignty of the State, the form of law or the total unit of domination; these are none other than the terminal forms" (1976: p. 120). If political anthropology has contributed to dereifying centralized political authority by showing the degree to which a focus on the form of state control has ultimately obscured the real diversity of figures of power, Foucault, for his part, has underlined the need to ask the question 'how' and to examine the exercise of power. To think of power in action, as a "way of acting upon actions" (2000b: p. 341), was also to challenge the traditional tools of political theory, which "had recourse only to ways of thinking about power based on legal models, that is: What legitimizes power? Or they had recourse to institutional models, that is: what is the state?" (2000b: p. 327). That meant delegalizing and deinstitutionalizing the approach to politics. Foucault made history play the role of the operator, allowing him to take a distant view of contemporary power and bring its constituent elements to light. He concluded that, in the seventeenth and eighteenth centuries, a new mechanism of power was invented that applied to people rather than to land. On the contrary, earlier theory of sovereignty was linked to a power exercised foremost on the land and its products, and not on the bodies of subjugated individuals. In the older vision, power aimed to seize goods and wealth – not working hours: "This theory makes it possible for power to be based on and around the physical existence of the sovereign and not at all on and around continuous and permanent surveillance systems" (2001: p. 186).

This brings us to one of Foucault's major themes: the art of governing, or in other words the practices by which we manage to 'structure the possible field of action of others' (2001: p. 341). One of the difficulties encountered by any anthropology of power comes from the permanent overlap that exists between 'the art of governing' – the concrete procedures that define the field of power – and a theory of sovereignty that claims both to establish the legitimacy of these procedures and to extend their meaning. Foucault introduces the concept of governmentality in order to better understand the modalities and the complexity of power in action. Political rationality and technologies of government lend specific substance to 'governmentality' that has been defined as "the composition and assembling of actors, flows, buildings, relations of authority into relatively durable associations mobilized to a greater or a lesser extent, toward the achievement of particular objectives by common means" (Rose, 2011: p. 148). From an anthropological perspective, the main value of the concept of governmentality consists in disentangling power from the discourse of sovereignty. Analysis in terms of governmentality privileges the dynamics of power, and their specific productivity, rupturing the traditional associations of power and sovereignty.

Foucault never conceptualized governmentality in terms of repression or bans. Criticizing Reich (1945) and Legendre (1974), he argues clearly that these works reduce the processes of power to a legal problematic rooted in sovereignty, which implies, among other things, a conception of power as negativity, or as a producer of the forbidden ("power is what says no") (2001: p. 423). The shift Foucault implements leads him to emphasize the plasticity of power relations, showing to what extent they are themselves caught up in other types of multiform and local relations, which leads to the further notion of micropowers. In a conference given at the Bahia university in 1976 (Foucault, 2001: p. 183), he criticized Lévi-Strauss and the Durkheimian school for focusing their conception of power on the notions of law and of prohibition. He opposed to this tradition the works of the French anthropologist Clastres as promoting a different vision in which power is considered as a specific 'technology' (2001: p. 184).

In some way, the genealogy of neoliberalism that the French philosopher developed in his *Collège de France lectures of 1978–1979* (2004) is an attempt to show that neoliberalism is not only a new age of the economy characterized by the triumph of financial capital and free-market values, but moreover a reconfiguration of governmentality, now focused on the *bios*. Beyond bringing to light the emergence of disciplinary techniques centered on the individual and his body, Foucault also shows how a new political technology, dealing with men in their multiplicity – the population – was put in place at the end of the eighteenth century. This technology, which he calls biopolitics, deals with the population as both a scientific and political issue. The interest taken in demography, the development of public hygiene, the institutions of assistance and insurance, and the taking into account of the relationship between man and the environment define a new configuration where the disciplinary dimension fades in favor of a project aiming to prolong life and regulate biological mechanisms. With the rise in the power of capitalism, these disciplinary work technologies acquired less direct procedures that allowed power to take over men as a group of living beings. Man was no longer just subjugated in his individual singularity, he was also controlled as a specimen of a population of living beings: the population as an undivided entity was the new subject of biopolitics.

The problematic of biopower has directly inspired recent research in anthropology. With respect to globalization, a great deal of commentary has been made about the ever-increasing imbrications of the local and the global. There have also been essential interrogations of the paradigm of the nation-state, which dominated the twentieth century but which was also rocked by the emergence of new modes of infra- and supranational governmentality. It is the model of territorial sovereignty that is at stake here, and the findings converge with Foucault's analyses, which suggest that power no longer has any particular affinity with territory, but is exerted above all on multiplicities. In the transnational space delineated by globalization, mobility and moving around, or what Appadurai (1996) designates as flows, play an essential

role. This explains the recent political focus on questions of immigration, humanitarian catastrophes, and the problem of refugees.

It is not surprising that anthropologists use concepts of governmentality and biopolitics to discuss the 'deterritorialization' of the contemporary world, because they provide a new and historical perspective on complex current situations. Research on diaspora bears witness to this. One example is the case of the Chinese from Hong Kong, as Aihwa Ong (1999) has analyzed them. At the time of British domination, they were considered to be British Dependent Territory Citizens (BDTC), and had the right to travel to Great Britain, but not to reside there. Since the retrocession of Hong Kong to China, they have British National Overseas status, and benefit from what Ong calls 'partial citizenship.' They have always been considered to be people of color, in the same way as Afro-Caribbeans, but are treated particularly well because of their economic dynamism. In 1990, the British government modified its immigration policy in order to confer citizenship upon certain Chinese residents from Hong Kong. This action was first of all a way of avoiding panic linked to the retrocession to China, which could have brought about a long-term destabilization of the market. It was in this way that 50 000 Chinese nationals and their families, belonging to the social elite in Hong Kong, could obtain British nationality. Those that had been selected were still young, between 30 and 40, had a high level of education, and through their activities and networks participated in flows of transnational capital. For Ong, the successive flip-flopping of the British authorities with regard to their citizenship reflects the implementation of a biopolitics that treats various population groups differently according to their place in the economic system.

Another line of research opened up by reflections on modern governmentality concerns the condition of populations deprived of any territorial claims or institutional status, those who are reduced to a 'bare life' condition, according to Agamben (1998), who extends Foucault's reflections on the matter. It is this bare life, disconnected from civic context, which constitutes the 'matter' of the masses of refugees, who are noncitizen residents established either permanently or temporarily in the territories of industrialized states, in the ghettos of the cities, or in refugee camps. According to Agamben (1998), this condition prefigures a form of community with no territory and no borders, in which residents' current refugee status prefigures their future possibilities. Legally vague, as far as identity and citizenship are concerned, the status of the refugee, which is being applied to growing masses of populations, dismantles the state–nation–territory triptych, inherited from the classical age, and puts into play a new definition of the subject/sovereignty relationship.

The *bare life* theme has been a subject of discussion in anthropology recently. This interest is due to the fact that from Kosovo to Rwanda researchers have generated ethnography of the effects of conflict and violence. The experience of suffering, destitution, and the denial of humanity in these extreme situations (Malkki, 1995; Kleinman et al., 1997; Agier, 2002), and also in the context of the marginalization that victimizes those abandoned at the margins of society (undocumented immigrants, victims of social exclusion, etc.), has led to reflections on the discourse and the practices through which contemporary governmentality deals with life (Fassin and Memmi, 2004).

Other research focuses on modes of intervention of the international community within the humanitarian domain. Here the idea is to reflect on the emergence of political actors whose relative autonomy results in new tensions, because their initiatives tend to continuously destabilize existing sovereignties. Likewise, on the sidelines of conflicts, 'nongovernmental' organizations, insisting that they are rooted in 'civil society,' perturb and add other levels of complexity (Abélès, 2006). One does not have to be an expert on the subject to see to what extent the opposition between politics and civil society is not very operational, because NGOs that claim to represent constituents are directly involved in a power relation of their own and thus attempt to exert power, or a 'mode of action on actions,' to repeat Foucault's formula (1984: p. 316). It can be stressed that many NGOS are not only involved in humanitarian intervention, but are also acting against the neoliberal logics that intensify poverty, suffering, inequalities between the North and the South, and so on.

The research carried out by anthropologists on armed conflicts and humanitarian interventions is exemplary of their political character. Concerning Kosovo, Pandolfi (2002) clearly shows how humanitarian interventions involve real investments by transnational organizations, which develop specific strategies and attempt to extend their control over local institutions. In theory, they are considered to be apolitical, but their actions fall within the scope of a power relation they contribute to shaping, with the more or less self-interested help of groups at the local level. We see then a configuration of power coming into existence that is more and more deterritorialized, leading the anthropologist to qualify it as 'migrant sovereignty,' insofar as the traditional nation-state apparatus no longer has a direct hold on the real elements being profoundly modified by the conflict.

Taking a more global point of view, what is at stake are processes that oblige us to profoundly modify a fixed conception of politics articulated around the concept of sovereignty. By proposing an approach that could be designated as pragmatic, in which governmentality is defined as a 'group of actions on possible actions' Foucault opened up a fruitful path of inquiry. It can provide a better understanding of the fact that state organization is now contrabalanced by other sources of power at the global and local levels. This phenomenon – the displacement of politics – has been commented on in terms of the weakening of the state, characterized as a rising 'governance without government' (Rosenau and Czempiel, 1992). Such governance involves not only formal political actors, but also other players from civil society. In a world increasingly threatened by various kinds of turbulence (Rosenau, 1990) – including terrorism, the proliferation of nuclear weapons, and mafia-orchestrated trafficking – the need for transnational governance is gradually becoming obvious. The increasing power of organizations aiming to provide types of regulation on a larger scale is a symptom that leads Badie (1999) to raise the prospect of a 'world without sovereignty.' This scholarship highlights the new power that supranational organizations have acquired, as well as the appearance of 'nongovernmental' organizations that have succeeded in occupying center stage

in contexts where authority was hitherto only held by the diplomacy of states. Scholars suggest that world of governance will be more and more a set of common rules imposed by an authority whose legitimacy will be recognized on a global scale. These observations reflect the development of a transnational level of governance. At the same time, one can question the functionalist perspective that informs these studies, as if the emergence of global politics could be interpreted as a complexification of institutions necessarily responding to a new globalized order.

The displacement of politics, that is, the fact that state is no longer the only protagonist and that the Hegelian dyad of state/civil society has lost its centrality at a conceptual level, is not only a matter of institutions and of sovereignty. It is not limited to the appearance of a new political scene in which old institutional powers have been replaced by newer ones, more able to handle the scalar change of globalization. Those who seek to extend political anthropology into the field of emerging transnational political forms find themselves facing the following conceptual dilemma: either they will be won over by the dominant institutionalist theory or they will realize the necessity of taking into account the specificity of these 'unidentified political objects,' as the former president of the European Commission Jacques Delors once described the European Union. There has been a global redefinition of the meaning and aims of political action. This redefinition is not simply cognitive. It also shows up in modes of action, in the constitution of organizational and institutional forms, in the selection of issues for public debate, and in the construction of epistemic spaces where this debate will happen. In other words, the redefinition is a matter of governmentality, in its original Foucaultian meaning.

If the focus of Foucault's work on biopower is the genealogy of the modern state, its analysis of governmentality provided a very powerful conceptual instrument and original interpretation of the rise of the welfare state. Introducing a dichotomy between an Oriental tradition of political philosophy and a Greek one, he considers the welfare state as the result of the convergence of these two traditions: here a "tricky adjustment between political power wielded over legal subjects and pastoral power wielded over live individuals" (2000a: p. 307) has been implemented. In one case, there is a perception of power or the relationship of the government to the governed, as illustrated through the metaphor of the shepherd leading his flock. This pastoral theme is prevalent in ancient oriental societies. The other tradition, illustrated notably by Plato in *The Statesman*, sees in the art of governing the capacity to achieve the unity of the city – to 'weave the finest of fabrics' (cited in Foucault, 2000a: p. 307). The welfare state was an unusual moment in history in that it managed to bring the two perceptions together in a single, cohesive whole – the state as 'centralized and centralizing power,' oriented toward the citizen, and 'pastoralism' as the 'individualizing power' (2000a: p. 300), aimed at subjects.

Foucault's analysis also helps us to better understand the displacement of politics that characterizes the contemporary forms of governmentality. In the era of globalization, the harmony between pastoral power and the centralizing state has disappeared. It is as though our perception and experience of politics is becoming bifurcated between a focus on the citizen/individual and a focus on the biopolitical subject. In fact, we can speak of a real transition, with a rise in preoccupations of life and *survival* at the heart of political action, while the issue of the Platonic city and the relationship of the individual to sovereignty, what I call *convivance*, is relegated to the background. The displacement can be summarized in the simple question that we constantly ask ourselves: 'what will our world consist of tomorrow?' It is this fundamental anxiety that not only alters our political representations but that also determines the space that can be allocated to political activity and the new places in which it is best exercised.

The place occupied today by transnational institutions such as the WTO, the UN, and the IMF is not due merely to their functionality in the global system. In fact, we are witnessing a reconfiguration of the political domain that does not content itself with developing a new mode of biopolitical governmentality. This is why theories traditionally based on the dialectic between state and civil society focus on changes in political scale and space in search of an impossible return to a harmonious civil order in which the forces of society could recover control over increasingly distant and mysterious powers and remediate their imbalances and inequalities. These theoretical and political expressions share a vision of harmonious living together, while the actual political practices we encounter are unfolding in the context of survival. To use Michel Foucault's distinction, these practices fall within the 'pastoral' dimension of power and apply less to 'civil subjects' than to 'living individuals.'

If one can speak of global governmentality in reference to this constellation of transnational institutions and organizations, it is not in the sense of an inclusive reordering, of a new power overlaying existing powers. This vision of things is part of the convivance perspective. Its final realization is 'empire,' a concept that falls within the same paradigm as the philosophical conception of the 'state' – a form intended to organize the communal life of subject citizens. Yet, in societies where threat is an integral dimension of the present, questions of life and survival now appear much more fundamental – thus, ideas of balance and order, justice and law only make sense in the context of a precaution-oriented viewpoint (Beck, 1992).

It is no accident that the theme of sustainability is now so intimately tied to theories concerning inequalities and the relationship between power and society. The separation of living individuals and civil subjects highlighted by Foucault has, in our own historical context, led to the emergence of the issue of survival and its political expressions which, while it connects to the traditional domain of 'international relations,' actually far exceeds it. There is now a dense, internalized space of anthropological anxiety regarding an assortment of threats, ranging from terrorism to the planet's ecological vulnerability – threats to which the political form of the nation-state form has been unable to give satisfactory answers or to guarantee human rights.

Global politics today thus casts us into a regime of anticipation and signals a lack of fulfillment. Global politics can neither be conceptually contained in terms of power balances nor considered as a superstate form. It is developing alongside the world of territorial division, without imposing itself on states and on traditional regimes of sovereignty as an overarching power. Between the nation-state and global politics,

we find the same polarity that I have described above as the tension between a regime of convivance, which places harmoniously living together as the highest aim of social beings, and a regime of survival. Today, global politics remains, to a high degree, dependent on the strategies of nation-states. At the same time, the specific development of new forms of transnational governmentality is modifying the distribution of power and this situation presents a new horizon for political anthropology.

Abstract

All human organizations have a government, but the most visible governments are those of nations and of public bodies in general. They are focal points of political life. They have three key functions, policy initiation, coordination, and implementation, although they are always at least somewhat constrained by forces in the society. They are typically compact, but vary widely in composition, organization, duration, powers: one of the crucial ways in which they differ is by the role of their leaders, be they presidents, prime ministers or, in a few cases, monarchs. Governments can be 'autocratic,' oligarchical, or democratic, democratic governments being essentially a development of the twentieth century: with these, parties have become involved, obviously if they are represented formally in the executive, singly or in coalition, but even if they are not. All governments, democratic or not, typically initiate policies, often under pressure of their leaders, whatever role parties and the 'civil society' may also exercise.

Governments are universal. They exist in every social organization: there is always a body, normally relatively small, which has the task of running that organization; but the most visible governments are those of nations and of other public institutions. With the decolonization process, independent national governments have come to rule practically the whole of the planet and they have more than doubled in number, from well under a hundred in the early 1950s to nearly two hundred at the beginning of the third millennium.

Problems of Definition

Being at the center of political life, national governments tend to be rather small and, often at least, compact. Yet it is not possible to circumscribe them neatly as their boundaries are not precise. In many cases, indeed most, an official list exists, but this list is typically not exhaustive, as key personalities, who may formally only be 'advisers,' but are in fact highly influential, tend not to be included. There are also often two or more 'levels' of the government: thus in the UK and in countries which have followed closely the British model, for instance, the 'cabinet' constitutes only an inner core, with 'ministers of state' and 'parliamentary secretaries' being below this core. In the USA, the government is typically referred to as the 'administration' or as the 'executive': however, both of these expressions remain imprecise with respect to those whom they cover.

It is therefore more appropriate to look for a definition in terms of the functions which national governments fulfill. In general, these are said to 'run the affairs of the nation,' although they only do this up to a point since they are helped and advised by a multiplicity of individuals and of groups, and, in modern democratic countries in particular, by parties and legislatures, while everywhere the bureaucracy is at their 'disposal.' One can in reality distinguish among three functions of governments. First, they have to elaborate realistic policies which can be implemented: this is the function of conception. Second, they have a function of implementation, as they must find the means of ensuring that the policies which have been elaborated are indeed turned into practice. There can be tensions between these two functions. The skills required to undertake each of them successfully are different: to conceive means to 'imagine'; to implement means to 'manage.' Yet governments have also a third function, that of coordination: they must ensure that the policies which are elaborated and implemented do not pull in different directions but are complementary.

Types of Government, Liberal-Democratic and Authoritarian

A 'revolution' in the characteristics of governments has occurred since the eighteenth century, when 'modern' government began. This 'revolution' has had two main aspects. First, there has been a massive increase in the complexity of governmental activities, as states have come to be increasingly involved in the economic and social life of countries, especially from the late nineteenth century to the 1980s. Second, many governments have come to be (or have had to be) responsive to the demands of citizens, in particular where the representative system had been introduced: for the first time in human history, these governments had to abide by rules based on liberal democratic principles and enshrined in constitutions. Admittedly, Greek cities, the Roman Republic, and, during the Renaissance, some parts of Italy, had experienced forms of 'limited' government; but only from the end of the seventeenth century did representative government take root in a nation, England, which hitherto had been a traditional monarchy, while, almost a century later, American independence marked the emergence of the first liberal Republic.

England and America were indeed the originators of the two main forms of constitutional government which have existed to this day, the cabinet system, which was gradually adopted in almost every Western European country and in the Commonwealth, and the presidential system, which spread to Latin America, though with only limited success. Thus, at the beginning of the third millennium, approximately half the

national governments could be described as being broadly responsive to their people. Meanwhile, in the rest of the world, including in many countries of Africa, of Asia and, at least in the past, especially up to the mid-1980s, of Latin America, governments have tended to be authoritarian. The Communist form was particularly harsh, both in what was the Soviet Union and in Eastern Europe up to the late 1980s, as well as in China and a number of other Asian countries: it was based on the dominance of a single party whose leaders formed the real government and controlled the formal executive. Independence from colonial rule which started in the 1950s and gathered momentum in the 1960s, especially in Africa, also led to many dictatorships, sometimes based on single-party arrangements but relying even more on the 'charismatic' figure of a president, often drawn from the military and having come to power through a coup. Admittedly, since the 1980s, a move towards responsive governments occurred in many countries hitherto ruled by dictatorships, in Latin America, in what had been the Communist block, in East and Southeast Asia and in parts of Africa; but authoritarian rule continued to characterize many countries of the contemporary world, sometimes on the basis of old-fashioned monarchical governments but more often on 'modern' types of dictatorships, in many cases of the military type.

The Organization of Governments: Cabinet and Presidential Systems. The Role of Leaders

Partly as a result of these differences, governments vary widely in organization, duration, composition, and powers. The distinction between the cabinet system and the presidential system remains the main one among liberal democratic governments, although there are variations within each of these two models and some cases are intermediate. The cabinet system is based on the division between a symbolic head of state, often a monarch, and a government, responsible to parliament, headed by a prime minister: the prime minister has to operate in the context of a collegial system in which those members of the executive who are part of the cabinet (normally referred to as 'ministers') are entitled to participate fully and collectively in decision-making: in practice, this is far from being always the case and there are substantial differences from country to country and within each country. Some cabinets are controlled closely by their prime minister, while others are more egalitarian. By and large, the British government and the governments of many Commonwealth countries tend to be tilted toward prime ministerial dominance, while a number of continental European governments, at least those which are based on complex party coalitions, give more elbow room to ministers. Yet, even though cabinet members may be more or less collectively involved, there is a real sense in which the government constitutes a team. A variation on this model is provided by the French system, in which the picture is somewhat complicated by the fact that the president, elected directly by the people, plays a significant part in policy making, at least when the party of the president also dominates parliament: this model has been adopted by some of the post-Communist governments of Eastern Europe as well as in the developing world.

The presidential system, on the other hand, is based on the separation of powers principle, with both president and legislature elected directly by the people. The president, as head of the executive, has thus greater leeway to organize the government in the way he/she wishes: this is particularly true in the USA. In some Latin American countries, on the other hand, the president has to an extent to take into account the desire of party leaders to play a part in the appointment of members of the executive. However, by and large, presidential governments are both constituted more independently from the parties and in particular from the parties in the legislature. They are also more hierarchical in character: the members of the government (typically known as 'secretaries') are responsible to the president for the department of which they are in charge (although in some cases the legislature can also censure them individually). They are not collectively involved in decision-making.

Governments are fashioned by their leaders. The twentieth century was characterized by the emergence of 'charismatic' rulers, including and perhaps above all in Communist countries, despite the fact that the Communist ideology is based on the notion that the economic 'substructure' is held to be paramount. 'Charismatic' or personalized leadership can also be found in liberal regimes, whether of the cabinet or of the presidential type. This has been the case not just of wartime leaders, such as Churchill or de Gaulle, but of rulers who attracted the imagination of whole populations, such as Kennedy.

The Duration of Governments

The duration of governments varies. The longest are those of the few remaining traditional regimes, in effect absolute monarchies, and those of some of the more 'modern' dictatorships: Communist governments, their leaders in particular, often remained in power for over a decade; on the other hand, most other leaders are only in office for a few years. The other government members often stay for even shorter periods: the average duration of ministers or secretaries is in the region of three to four years, with a substantial proportion of them being truly transient and remaining in government for a year or less.

Career Patterns

The composition of governments also varies. Some of these, primarily where there is a cabinet system, include almost exclusively professional politicians, men and women who have been active in a political party, have then been elected to parliament and have joined the ranks of the executive after a few years on the 'backbenches.' Other government members are 'technicians,' more often drawn from the public sector than from the private sector: their career in politics tends to last a few years only and they return to other public or private jobs after their stint in government. Moves of this kind occur less frequently in cabinet systems than in presidential systems, where, as we noted, the head of the state has more freedom to pick and choose whom he or she wants to appoint; they also occur in many authoritarian governments, though, in these, military men are often side by side with civilian 'managers.'

Variations in career patterns are associated with differences in social background. In general, except where social democratic parties are frequently in power, as well as in the past Communist systems, men and women with a working class background are rare: lawyers, teachers, and managers form the bulk of the civilian members of governments. Only in the last decades of the twentieth century and in some countries, mainly Northern European, have women had more than a token share of governmental posts, especially in such key departments as those of foreign, economic, or internal affairs.

The Impact of Governments: An Unresolved Question

There is debate about the extent to which leaders and governments affect the countries which they rule. As their careers are often short, it is suggested that members of the higher civil service, together with the lobbies which gravitate around them, play a key part in decision making. As a matter of fact, it has not been possible so far to determine precisely the impact of leaders and members of governments even when they stayed in power many years: environmental factors, both internal and external to the country concerned, must be taken into account. Yet some leaders at least, whether 'harsh,' such as Lenin or Stalin, or 'good,' such as Roosevelt or Churchill, had a major influence on the destinies of the countries which they ruled and indeed of the world. What can only be said is that there are massive variations in impact, as there are major variations in the characteristics of governments and in particular in their responsiveness, organization, duration, composition, and complexity.

Grammatical Agreement

Dieter Wunderlich, University of Düsseldorf, Germany; and Centre for General Linguistics (ZAS) at Berlin, Germany

Abstract

In grammatical agreement, a governing predicate (verb), the members of a noun phrase, or an anaphorically dependent pronoun can bear similar ϕ-feature values (person, number, gender) as the controlling noun. Syntactic theories assume a narrow association of case and agreement (disproved in Indo-Aryan), while lexicon-based accounts work with referential indexes in the syntax–semantics interface. In long-distance agreement, a matrix verb is linked to an object noun occurring in a dependent clause; all theories assume some specific local mechanism for the matrix verb to have access to the dependent-clause noun. Finally, some constraints on agreement are considered.

Introduction

Grammatical agreement is a phenomenon in which co-occurring word forms have similar or the same values of number, gender, and person related to some entity. So all words in (1a) are singular (sg), while all words in (1b) are plural (pl); moreover, several words in (1a) are feminine (f), while the corresponding words in (1b) are masculine (m). (The values that a word form bears are indicated by superscripts.) The examples in (1) to (4) show some common agreement relations.

1. French
   a. La^{fsg} fillette^{fsg} est^{3sg} belle^{fsg}.
      'The girl is beautiful.'
   b. Les^{pl} garcons^{mpl} sont^{3pl} beaux^{mpl}.
      'The boys are handsome.'
2. Italian
   a. Tu^{2sg} l'^{3sg} hai^{2sg} vista^{fsg}.
      'You have seen her.'
   b. (io^{1sg}) li^{3mpl} ho^{1sg} visti^{mpl}.
      'I have seen them (masc).'
3. Finnish
   a. Taina löysi minun$^{1sg}{}_{GEN}$ kirja-ni^{1sgPoss}.
      'Taina found my book.'
   b. Taina löysi heidän$^{3pl}{}_{GEN}$ kirja-nsa^{3Poss}.
      'Taina found their book.'
4. German
   a. Ein kleines^{nsg} Mädchen^{n} sass^{3sg} auf der Treppe, und es^{nsg} lachte.
      'A little girl sat on the stairs, and she laughed.'
   b. Ein kleiner^{msg} Junge^{msg} stand^{3sg} daneben, und er^{msg} heulte.
      'A little boy stood beside, and he cried.'

In (1), the definite article agrees with the noun, and both the copula and the predicative adjective agree with the subject. If one item of (1a) is exchanged by the corresponding item of (1b), the sentence becomes ungrammatical (e.g., **la fillette sont belle*). (2) shows two agreement relations intermingled: The auxiliary agrees with the subject pronoun, while the participle agrees with the preceding object clitic. (3) is an example where the possessed (Poss) noun agrees with the genitive (GEN) possessor. In (4), the pronoun in the second clause agrees with the antecedent noun phrase in the first clause. Note that *Mädchen* 'girl' is a neuter (n) noun, triggering a neuter pronoun, although it refers to a female being; in contrast, English pronouns are always selected on semantic grounds.

Grammatical agreement comes as an interplay of morphological, syntactic, and semantic aspects (Anderson, 1998; Lapointe, 1988; Corbett, 1994, 1995, 1998; Pollard and Sag, 1994). Morphologically, some words are inflected for agreement. Syntactically, constituents stand in the agreement relation if the words they consist of bear corresponding information. Semantically, agreement serves to keep record of discourse referents: Only constituents that relate to the same referent can overtly agree with each other (Lehmann, 1982). The sentences in (1) are about a single person or a group of persons, while those in (2) are about two referents standing in a 'see'-relation.

Siewierska (1999) distinguishes three types: "(1) Anaphoric agreement markers are in complementary distribution with free nominal or pronominal arguments; (2) ambiguous agreement markers occur obligatorily both in the presence and absence of free nominal or pronominal arguments; (3) grammatical agreement markers are obligatory, like ambiguous markers, but, unlike ambiguous or anaphoric markers, must necessarily be accompanied by overt nominal or pronominal arguments." Accordingly, Italian shows ambiguous agreement, while German shows grammatical agreement.

Generally, agreement relations can be found among the following elements:

1. (noun phrase (NP)-/determiner phrase (DP)-internally) determiner and noun, attribute and noun, possessor and possessed noun;
2. (clause-internally) a predicate and one of its arguments: verb–subject, verb–object, preposition–object, predicative-argument;
3. (cross-clausally) a pronoun/anaphora and its antecedent.

The categories that appear in these relations are called ϕ-features, including person (first, second, third, inclusive = 1 + 2), number (singular sg, plural pl, dual), and gender (e.g., feminine f, masculine m, neuter n).

Nouns and pronouns (including pronominal affixes and clitics) function as the controller (source or probe) of an agreement relation in virtue of their features. Nouns are inherently classified for gender (or noun class), and sometimes also for number (cf *scissors*, *trousers*, *mice*, *men*, *brethren*), whereas pronouns are inherently classified for person and number, and sometimes also for gender. The inherent classification is often semantically

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53034-7

based: Female beings are represented by feminine nouns but male beings by masculine nouns; aggregates are represented by plural nouns; addressees are represented by second-person pronouns, while speakers by first-person pronouns. Otherwise, feature assignment can be purely grammatical (obvious in genders such as French *lune*^{f}, *soleil*^{m} versus German *Mond*^{m}, *Sonne*^{f} (both 'moon, sun,' respectively)), and then even override the semantic default (as in German *Mädchen*^{n} 'girl').

The grammatical elements that agree with the noun or pronoun are said to be the agreement targets (=controllees); in (1a), the article *la* is the target of *fillette*, which is feminine, and both the copula *est* and the adjective *belle* are targets of the DP *la fillette*, which is fsg. The agreement features of controller and target do not have to be identical, but they must be compatible with each other (such as `3sg∪fsg⇒3fsg vs 3sg∪fpl⇒*`). In order for a complex DP to be the controller of an agreement relation, the features of the noun and the other DP-internal elements have to be unified. For short, ϕ-features index the referential elements of a discourse (pronouns and DPs), as well as the categories that predicate of these elements.

In the wide sense, one speaks about 'agreement' if, e.g., the verb bears information about arguments. Sometimes this information is clearly pronominal; sometimes it is less than that. In Italian, *ho*^{1sg} *vista*^{fsg} is possible alongside with *io*^{1sg} *l'*^{3fsg} *ho*^{1sg} *vista*^{fsg}, so that one can conclude the information is pronominal. In German, one cannot drop the pronouns; *habe*^{1sg} *gesehen* ('have seen') is clearly incomplete. Forms such as *ich*^{1sg} *habe*^{1sg}, *du*^{2sg} *hast*^{2sg} 'I have, you have,' however, are redundant because the information of the subject pronoun is doubled by the agreement morphology. Redundancy is one of the 19 criteria of canonical agreement offered by Corbett (2003a); in that sense, agreement in German is more canonical than agreement in Italian.

If the verb bears information about just one argument, it is usually about the nominative argument (the subject in nominative (NOM)–accusative (ACC) patterns, or the object in ergative (ERG)–absolutive (=nominative) patterns). That the Italian participle can bear information about the object has ultimately to do with the fact that these participles also occur in passive constructions.

The notion of 'agreement' is sometimes used in a still broader sense, including other types of correspondences as well, for instance, case concord in (5) and sortal correspondence in (6).

5. a. Latin: DP-internal case concord
   Illa^{fsg}-m$_{ACC}$ femina^{fsg}-m$_{ACC}$ bella^{fsg}-m$_{ACC}$ videbam.
   'I saw that beautiful lady'
   b. Finnish: DP-internal case concord
   tuo-n$_{GEN}$ nariseva-n$_{GEN}$ tuoli-n$_{GEN}$ alla
   that squeaky chair under
   'under that squeaky chair'
   c. German: Case concord between the predicative noun and its argument
   Man nannte ihn$_{ACC}$ einen Idioten$_{ACC}$; er$_{NOM}$ wurde ein Idiot$_{NOM}$ genannt.
   'He was called an idiot'
6. The horse neighs; the dog barks; the cock crows.

These relations, however, differ in many respects from agreement described above, and, therefore, are not included here. Case reflects the grammatical role of a constituent (subject or object), rather than its referential status, whereas sortal correspondence is based on much finer semantic distinctions than ϕ-features can offer.

Theoretical Accounts

Several theories have been launched to account for agreement phenomena. In a first systematic attempt, the constituents introduced by a phrase structure rule, such as S → DP + VP, are indexed with the same set of ϕ-feature values:

7. a. $S \rightarrow DP^{\phi i} + VP^{\phi i}$ (subject + verb phrase)
   b. $DP^{\phi j} \rightarrow D^{\phi j} + NP^{\phi j}$ (determiner + noun phrase)

This account does not allow the instantiation of different (although still unifying) feature values, as in the French example (1), in which one constituent is fsg and another one is 3sg, and it does not account for anaphora–antecedent agreement, because these elements do not originate from a common syntactic node. On the other hand, this account is not specific enough, because it would describe case concord with the same means. Moreover, the claim that ϕ-feature values distribute along with phrase structure rules seems rather arbitrary.

Notice that (7) is symmetric between controller and target. In contrast, general phrase structure grammar proposed an asymmetric analysis: Controller elements can inherit a feature structure AGR lexically, whereas target elements (mostly the functors) receive such a structure only by morphological affixation; the distribution of AGR-features within a clause is then checked by a general control-agreement principle (Gazdar et al., 1985). Again, this theory is both too general and too restricted with respect to agreement.

In the Chomskyan framework of *Principles and Parameter Theory*, later replaced by *Minimalist Syntax* (Chomsky, 1995), the bearer of agreement features are functional categories represented by independent syntactic projections (Laka, 1988; Pollock, 1989; Chomsky, 1991). Consider the schematic structure in (8). This structure describes subject–verb agreement when the AGR-node is identified with AGRS, which is specified for certain ϕ-feature values, as well as for case features (such as NOM). In order to get marked for subject agreement morphologically, the verb stem must move to AGRS, while the subject DP moves into SPEC.AGRS, where it receives nominative case (both movements leave a trace, which is coindexed in (8)). Similarly, AGRO is responsible for object–verb agreement as well as accusative case, and AGRPOSS is responsible for possessor–noun agreement as well as genitive case. Regardless of various modifications in detail, the basic idea remained the same: There is one syntactic configuration that determines both case and agreement. Agreement, as well as case, is checked between AGR and

SPEC.AGR (and both must be licensed by a particular argument role of the verb or noun).

8.

This configuration deals with agreement as an additional structure superimposed on argument structure (such as subject–verb, object–verb, or possessor–noun). It is unclear what additional structure would account for agreement with attributes, adverbs, secondary predicates, or dependent objects. More recently, Chomsky (2000, 2004) proposed to dispense with additional AGR structures and syntactic Spec–Head relations. Agreement is now assumed as a relation between a probing head and a target goal, which is in the probe's c-command domain. Note that the terminology has been shifted: Now the controller (say, a subject NP) is called target, and the controllee (the verb) is called probe. TENSE rather than arbitrary AGRS is the category responsible for subject agreement, and little *v* (which c-commands VP) for object agreement. The probing head bears unvalued ϕ-features that must find their values within the respective domain.

For most syntacticians, agreement is a local phenomenon and part of narrow syntax. The cross-sentential anaphora–antecedent relation certainly is nonlocal and cannot be captured syntactically. There are more instances of nonlocal ('long-distance') agreement between matrix and embedded clauses, where it is argued that they can be handled locally (see below). In view of these more complex phenomena, Bobaljik and Wurmbrand (2005) come to the conclusion that "agreement is with a (LF) phasemate" (where a phase is something like a clause and LF is 'logical form'); thus, for these authors, agreement is postsyntactic (see also Bobaljik, 2008), a position that is not so far from lexically based accounts.

Another problem for syntactic accounts comes from the assumption that agreement and case assignment are the two sides of the same coin. If a verb agrees with just one argument, more than often it is the nominative argument: In a nominative-accusative language, the verb agrees with the subject, and in an ergative-nominative ('absolutive') language with the object. Hindi is compatible with that correlation even if it is more complex in showing two types of differential realizations. Verbs select ergative for the subject only in the perfective, and accusative for the object only if that is definite or human specific. Thus, a transitive verb of Hindi can show ERG-ACC or ERG-NOM in the perfective, but NOM-ACC or NOM-NOM in the imperfective. The agreement rule is 'agree with the highest nominative' (which is the subject in the imperfect but the object in the ERG-NOM pattern); there is no agreement in the ERG-ACC option. Thus, Hindi very clearly exemplifies a narrow correlation between case and agreement.

But other Indo-Aryan languages (with millions of speakers) behave totally differently, even if they have similar case patterns. The Nepali verb agrees with the ergative subject in an ERG-NOM pattern (9a, Deo and Sharma, 2006), while in the opposite, the Kutchi-Gujarati perfective verb agrees with the focused accusative object in a NOM-ACC pattern (9b, Patel, 2007), i.e., contrary to what is expected, the verb agrees here with the marked rather than the unmarked argument in terms of case. There obviously is no case-agreement correlation in general. Wunderlich (2012) proposes an analysis where case and agreement, based on the same argument ranking, are determined by different constraint rankings (such as *ERG ≫ ERG! or ERG! ≫ *ERG; AGR(S) ≫ AGR(O) or *AGR(S)/*context* ≫ AGR(S) ≫ AGR(O), etc.). Nepali combines ERG! ≫ *ERG with AGR(S) ≫ AGR(O), while Kutchi-Gujarati combines *ERG ≫ ERG! with *AGR(S)/+perf ≫ AGR(S) ≫ AGR(O) (ERG! = realize ergative; *ERG = do not realize ergative, etc.).

9. Agreement with case-marked arguments

a.	Mai-le mero	luga:	dho-en.	*Nepali*
	I-ERG my	clothes.NOM	wash-PERF.1sg	
	'I washed my clothes'			
b.	Reena	chokra-ne	mar-ya.	*Kutchi-Gujarati*
	Reena.f.NOM	boys-ACC	hit-PERF.mpl	
	'Reena hit the boys'			

The relation between controller and controllee is asymmetric, as well as the (reversed) relation between probing head and goal. Yet, the agreement relation itself is symmetric: Agreement holds if the pieces of information on the controller and on the head are compatible. Thus, a unification-based approach might be promising.

Following the idea that ϕ-features keep record in what the individual referents are predicated of, agreement is seen as a mechanism that rests on the normal composition procedures; there is no need for a special syntax of agreement. In this spirit, agreement was analyzed as a syntax–semantics interface phenomenon in *Head-driven Phrase Structure Grammar* (HPSG; Pollard and Sag, 1994) as well as in *Lexical Decomposition Grammar* (LDG; Wunderlich, 1994, 1997). In HPSG, all grammatical information of lexical items or more complex forms is encoded by means of feature structure; the ϕ-features that are shared in an agreement relation (regardless of whether they are lexically inherent or morphologically introduced) form a substructure INDEX (as part of CONTENT), and when a clause is composed, the relevant INDEX structures are unified.

In LDG, all morphological and phrasal composition is determined by the theta structure of lexical items, constituted as a list of lambda abstractors related to the semantic form (a partial semantic representation). In this theory, ϕ-features are associated with (indexed to) individual variables under a binder, such as the λ-abstractor or the Russellian iota operator 'ι'; in the process of composition, these indexes are unified at the common binder of the variables in question. This is illustrated in (10), representing the composition of Latin *illa femina bella* 'that beautiful woman' from three individual entries; unification is represented by the sign '∪.'

10. D: *illa* — $\lambda P\ \iota z^{fsg}\ \{\text{DISTAL}(z)\ \&\ N(z)\}$
N: *femina* — $\lambda x^{fsg}\ \text{WOMAN}(x)$
A: *bella* — $\lambda y^{fsg}\ \text{BEAUTIFUL}(y)$
NP: $\lambda x^{fsg \cup fsg}\ \{\text{WOMAN}(x)\ \&\ \text{BEAUTIFUL}(x)\}$
DP: $\iota z^{fsg \cup fsg \cup fsg}\ \{\text{DISTAL}(z)\ \&\ \text{WOMAN}(x)\ \&\ \text{BEAUTIFUL}(x)\}$
'that entity (referred to by fsg) that is distal, a woman, and beautiful'

Long-Distance Agreement

In the Italian example (11), the subject agrees locally with the auxiliary, and nonlocally with the participle embedded in a dependent infinitive clause. The agreement facts thus indicate that 'have fear' and 'be arrived too late' predicate of the same individual referent. If one assumes that *ha paura* is a subject-control verb, the identity of arguments follows from the lexical entry of control verbs; by functional composition, the argument variable of 'be arrived too late' then fuses with the argument variable of *ha paura*, and the ϕ-features must unify, as shown in (11c).

11. LDA with Italian participles

a. Giovanni^{3msg} ha^{3sg} paura di essere arrivato^{msg} troppo tardi.
G. has fear to be arrived too late
'Giovanni fears to have arrived too late'

b. I ragazzi^{3mpl} hanno^{3pl} paura di essere arrivati^{mpl} troppo tardi.
'The boys fear to have arrived too late'

c. ha paura — $\lambda P\ \lambda x^{3sg}\ \text{FEAR}(x,P(x))$
di essere arrivato troppo tardi — $\lambda y^{msg}\ \text{ARRIVED_TOO_LATE}(y)$
$\lambda x^{3sg \cup msg}\ \text{FEAR}(x,\text{ARRIVED_TOO_LATE}(x))$
'the property (of 3msg entities) of fearing to have arrived too late'

Some of the elements may be underspecified for f or sg, but any other specification would lead to ungrammaticality (such as **illa femina bellus*^{msg}). Notice that the indexed information becomes relevant only when semantic composition takes place; therefore, this account indeed locates agreement at the syntax–semantics interface. Index unification itself is symmetric; all asymmetries result from the syntactic categories.

This approach can easily be extended to all other kinds of agreement, taking into account the specific mode of composition. If one forms the assertion *illa femina bella modesta est* 'that beautiful woman is modest,' one predicates 'be modest' ($\lambda u^{fsg}\ \text{MODEST}(u)$) of the result of (10), and if one continues with the pronoun *ea*^{fsg} 'she,' *illa femina bella* is a possible antecedent (referring to the same person) because the ϕ-features are compatible.

Another language well known for long-distance agreement (LDA) is Hindi (Mahajan, 1989; Wunderlich, 1994; Boeckx, 2004; Bhatt, 2005; Chandra, 2007). An imperfective control verb such as *caah-t-* 'want' agrees (together with a possible auxiliary) with the nominative subject (12a), while the perfective variant agrees with the embedded nominative object (12b) because ergative on the subject blocks agreement with the subject. There are two further possibilities, namely, that no agreement takes place in the perfect and the verbs get the default ending msg (12c), or that the embedded verb agrees with the object in the imperfect (12d, not available in all dialects). The respective acceptability rates are 95%, 88%, 78%, and 67% according to a study by Bornkessel-Schlesewsky et al. (2008).

12. LDA with Hindi control verbs

a.	Raam^{msg}	roTii^{fsg}	khaanaa^{msg}	caahtaa^{msg}	thaa^{msg}	
	Ram	bread	eat.INF	**want**.IMPF	**be**.PAST	
	'Ram habitually wanted to eat bread'					
b.	Raam ne	roTii^{fsg}	khaanii^{fsg}	caahii^{f}	thii^{fsg}.	LDA
	Ram ERG	**bread**	**eat**.INF	**want**.PERF	**be**.PAST	
	'Ram had wanted to eat bread'					
c.	Niinaa^{fsg} ne	roTii^{fsg}	khaanaa^{msg}	caahaa^{msg}	thaa^{msg}.	
	Ram	ERG bread	eat.INF	want.PERF	be.PAST	
	'Ram had wanted to eat bread'					
d.	Raam^{msg}	roTii^{fsg}	khaanii^{fsg}	caahtaa^{msg}	thaa$^{msg.}$	
	Ram	**bread**	**eat**.INF	**want**.IMPF	**be**.PAST	
	'Ram habitually wanted to eat bread'					

Under what condition the option b or c is selected is controversially discussed. According to Chandra (2007), LDA is possible only with specific objects, while Bhatt (2005) states that the embedded object can get scope over the matrix verb only when LDA takes place. Thus, 'Naim wanted to read every book' with no agreement only allows the reading *want* > ∀, while the LDA version b allows both readings *want* > ∀ and ∀ > *want* (with the latter being preferred). Bobaljik and Wurmbrand (2003) observed a similar pattern in Itelmen; see (16c) below.

This suggests that LDA is possible by reconstruction, where a verb complex is formed and the argument structure of the lowest verb is inherited to the result. The analysis of (12b) is sketched in (13). The suffix *-ii* in *khaan-ii* instantiates the feature complex fsg, which may be associated with either argument (the association with the subject 'u' being the default), whereas the perfect form *caah-ii* instantiates f, which cannot be associated with the argument role assigned ergative. In this context, only the second alternative of *khaanii* can survive because of unification.

13.

khaanii	*caahii*
$\lambda y\ \lambda u^{fsg}$ EAT(u,y)	
$\lambda y^{fsg}\ \lambda u$ EAT(u,y)	$\lambda P^{f}\ \lambda x$ WANT(x,P(x)) ERG

$\lambda y^{fsg \cup f}\ \lambda x$ WANT(x,EAT(x,y))
ERG

Other types of verbs in Hindi that make LDA possible by forming verb complexes are raising-to-subject verbs like 'seem' in (14a), raising-to-object verbs like 'see' in (14b), light verbs like 'let' in (14c), and modals with a lexically marked subject like 'should' in (14d). Here, again, ergative/accusative blocks subject agreement, and a verb complex is formed.

14. More LDA verbs in Hindi

a.	Raam ne	roTii^{fsg}	khaayii^{f}	lagtii^{f}	thii^{fsg}.	
	Ram-ERG	bread	eat.PERF	seem.IMPF	be.PAST	
	'Ram seemed to have eaten bread.'					
b.	Raam ne	billii^{fsg} aatii^{f}	dekhii^{f}	thii^{fsg}.		
	Ram-ERG	cat	come.IMPF	see.PERF	be.PAST	
	'Ram had seen a cat coming.'					
c.	Nadia-ne	sarosh-ko	gaaRii ^{fsg}	chalaa-ne	d-ii ^{fsg}	
	Nadia-ERG	Sarosh-ACC	*car-F.SG*	drive-GER.OBL	*let-PERF.F*	
	'Nadia let Sarosh drive car.'					
d.	Raam-ko	davaaii^{fsg}	khaa	lenii^{f}	chaahiye	thii^{fsg}.
	Ram-ACC	medicine	eat	take.INF	should	be.PAST
	Ram should have taken medicine.					

In principle, LDA is recursive: The following sentences, although not usual, are grammatical (Shravan Vasishth p.c.).

15. a. Raam ne larki^{fsg} aatii^{f} dekhnii^{fsg} chaahii^{f}.
Ram-ERG girl come.IMPF see.INF want.PERF
'Ram wanted to see a girl coming.'
b. Raam-ne har kitaab^{fsg} parhnii^{fsg} chaahii^{f} lagtii^{f} hai.
Ram-ERG every book read.INF want.PERF seem.IMPF be.PRES
'Ram seemed to have wanted to read every book.'

LDA is found in many more languages. In Basque, the auxiliary (which encodes up to three arguments) agrees with the number of the embedded object (16a, Etxepare, 2006). In Itelmen, a Chukotko-Kamchatkan language, the matrix verb agrees with person.number of the direct or indirect embedded object (16b,c, Bobaljik and Wurmbrand, 2003, 2005); (16c) shows the same scopal reading as found in Hindi. Note that the matrix verbs here are control verbs, i.e., restructuring verbs forming a verb complex.

16. LDA with restructuring verbs in Basque (a) and Itelmen (b,c)
a. [liburu-ak itzultze-ko] eskatu dizkidate
book-**pl**.NOM give-back asked have.3plERG.1sDAT.**3pl**NOM
'They asked me to give back the books.'
b. əntxa-βum = nIn kəma-nk nən^{l}č i zəl-es.
forget-**1sg** = 3.CL **me**-DAT fish INTERJ give-INF
'He forgot to give me (a) fish.'
c. t'-əntxa-ceʔn [miλ okno?-n sop-es]
1sg-forget-**3pl**.OBJ [all window-**pl** close-INF]
'I forgot to close all the windows.' (∀ > *forget*)

Another group of LDA languages includes the NE Caucasian Daghestan languages. In Tsez, the matrix verb agrees with the gender class of the embedded object (17a); Polinsky and Potsdam (2001) state the following conditions: "(i) The embedded clause must be in the absolutive position, (ii) the trigger must be the absolutive argument of the embedded clause, (iii) the absolutive NP must be the topic of the embedded clause." In Khwarshi, the matrix verb likewise agrees with the gender class of the embedded object, but under slightly different conditions: The embedded object must be either topic (17b) or focus (17c) and it must be moved into initial position (Khalilova, 2007). Note that 'know' is not a restructuring verb, because the embedded clause is finite. Just to illustrate what LF-'phasemate'-ship (Bobaljik and Wurmbrand, 2003) here means, (17a) might be paraphrased as 'the mother knows of the bread (=topic) that the boy ate.'

17. LDA with nonrestructuring verbs in Tsez (a) and Khwarshi (b,c)
a. eni-r [už –aa magalu b-aac' -ru-λi] **b**-iy-xo
mother-dat boy-erg bread.**III**.NOM III-eat-PASTPARTIC-NOML **III**-know-PRES
'The mother knows that the boy ate the bread.'
b. Zihe-n už-a-l b-iq'-še **b**-iti-xx-u.
cow(**III**)-TOP boy.OBL-LAT **III**-know-PRES III-divide-CAUS-PASTPARTIC
'The boy knows that the cow was stolen.'
c. K^{ʔ}aba zihe b-ot'uq'q'-u **b**-iq'-še už-a-l.
black cow(**III**) III-come-PASTPARTIC **III**-know-PRES boy.OBL-LAT
'The boy knows that the black cow has come.'

Despite theoretical differences, all accounts of LDA are agreed that apparent nonlocal agreement is in fact local. Either the matrix verb and the embedded verb form a verb complex in which subject and embedded object are clausemates (clause union in Hindi, Basque, Itelmen, etc.), or the embedded object is moved into a peripheral position (topic or focus) in which it is accessible to the next higher domain (in the spirit of Chomsky's (2000) edge condition) – which is the case in the Daghestan languages (17).

Since LDA in the sense of (16) always is lexically triggered by the matrix verb (note that Kutchi-Gujarati has just one lexical item of this sort, namely *par* 'have to,' according to Patel (2007)), lexically based accounts like HPSG and LDG seem especially suitable for the analysis of these constructions: There is something in these lexical items that makes them able to 'see into' a dependent clause. Furthermore, discourse categories like topic and focus (to be dealt with in discourse-semantics) seem to play an important role for connecting matrix and dependent clause. In contrast, syntactic accounts assuming that agreement is mediated by extra-syntactic AGR heads (like Mahajan, 1989) come into trouble to analyze LDA; therefore, the syntactic minimalism in Chomsky (2000) was a major step for approximating syntactic theory to lexical frameworks.

Constraints on Agreement

Most languages have the possibility of 'no agreement' in using a default verb form that otherwise could agree such as neuter, third person, or masculine singular. In these cases, the feature complex introduced by the verb form is not associated with an argument variable. Since in German only nominative forms can agree with the verb, agreement is possible in (18a), but is blocked in (18b), so that only the default form friert$^{\varnothing}$, lacking an index value, can appear.

18. a. Ich^{1sg} friere^{1sg} 'I am cold'
    b. Mich^{1sg} *friere^{1sg}/*friert^{3sg}/friert$^{\varnothing}$ 'I am cold'

Not all languages use agreement. Clearly, a language such as Chinese with nearly no morphology cannot have agreement, but also Malayalam (a Dravidian language spoken in Kerala, SW India), which shows rather rich derivational morphology and also morphological case, nevertheless does not have any agreement. Moreover, the extent to which agreement is used differs from language to language. Not only may the number of distinctions in the gender, number, and person categories, as well as the richness of inflectional affix inventories vary, it also depends on language-specific grounds in which contexts agreement is obligatory, optional, or even forbidden.

Hungarian marks plural on nouns, adjectives, and verbs. However, adjectives only agree with a noun when they are used predicatively (19a,b). Surprisingly, in the context of a numeral, which inherently contains the concept of plurality, the noun must not be marked for plural (19c). Furthermore, a predicative adjective or verb only agrees with a subject phrase that is overtly marked for plural, see (19d,e).

19. Hungarian plural agreement
    a. gyors hajók^{pl}/*gyorsak^{pl} hajók^{pl}
       'fast ships'
    b. Ezek^{pl} a hajók^{pl} gyorsak^{pl}/*gyors^{sg}.
       'These ships are fast.'
    c. öt hajó^{sg}/*öt hajók^{pl}
       'five ships'
    d. Az öt hajó^{sg} gyors^{sg}/*gyorsak^{pl}.
       'The five ships are fast.'
    e. Az öt nagynéni^{sg} sört iszik^{3sg}/*isznak^{3pl}.
       DET five aunt beer drinks
       'The five aunts drink beer.'

Since Hungarian has the plural forms *gyorsak* 'fast' and *hajók* 'ships,' these forms must somehow be blocked in (19a,c). Ortmann (2000) proposed that the agreement facts in (19) follow from the interaction of economy and expressivity principles. More specifically, if one assumes the economy constraint 'avoid multiple expression of plurality in NPs' to rank above the expressivity requirement 'mark plural on the noun!,' both *gyors hajó* and *gyorsak hajók* would violate one of these constraints, and *gyors hajók* turns out to be the optimal form in a context in which more than one ship is meant. In contrast, the singular form *öt hajó* is preferred because the numeral *öt* 'five' already expresses plurality; in this case, it is better to violate the lower-ranked constraint rather than the higher-ranked one. The tableau illustrates that the winner exhibits the fewest violations of higher-ranked constraints.

	Several fast ships are meant	*Avoid multiple expression of plurality in NPs!*	*Mark plural on the noun!*
a.	gyors hajó^{sg}		Violated
⇒	gyors hajók^{pl}		
	gyorsak^{pl} hajók^{pl}	Violated	
b. ⇒	öt^{5} hajó^{sg}		Violated
	öt^{5} hajók^{pl}	Violated	

If plural is unmarked on the noun, the noun phrase is sg and thus incompatible with a plural verb form, as shown in (19e).

As we have seen, Hungarian (unlike English and German) avoids NP internal agreement. There are also languages that avoid subject–verb agreement, even if they have the suitable affixes. Kurdish, for instance, marks plural only on the verb, see (20). In contrast, Georgian marks plural on the verb only if the subject refers to animate beings, see (21).

20. Kurdish
    Mirov/*mirovan^{pl} hat-in^{3pl}.
    man come.past-3pl
    'The men came.'

21. Georgian
    a. Burt-eb^{pl}-i goravs^{3}/*goraven$^{3pl.anim}$.
       ball-pl-NOM roll
       'The balls are rolling.'
    b. Knut-eb^{pl}-i goraven$^{3pl.anim}$/*goravs^{3}.
       kitten-pl-NOM roll
       'The kittens are rolling.'

These few examples show that the implementation of agreement considerably varies from language to language.

Grammatical Relations

This article is a revision of the previous edition article by A.E. Kibrik, volume 9, pp. 6342–6348, © 2001, Elsevier Ltd.

Abstract

Grammatical relations refer to grammatical functions, such as subjects and direct/indirect objects, and are among the most extensively assumed concepts in linguistic analyses. Despite their wide applications, traditional grammar does not successfully define grammatical relations in a precise manner. Modern linguistics, however, has achieved such a task in the formal or the functional approaches to language. Grammatical relations are now understood as a cluster of properties involving (functional-)thematic roles, cases, and syntactic derivations regarding designated argument positions.

Grammatical relations (or grammatical functions), such as subject, direct object, indirect object, refer to nominal elements that appear in designated structural positions in relation to verbal elements, in particular between subjects and predicates, and between verbs and objects. Grammatical relations can be characterized in terms of meanings they express, in terms of their morphosyntactic properties, and/or in terms of their structural positions in formal analyses of language. Therefore, the term grammatical relations may refer to a cluster of different properties. For example, at least three types of arguments are typically referred to as 'subjects' in the linguistic literature: thematic subject, case subject, and structural/grammatical subject. Although these notions may overlap, it is important to identify each of them when studying grammatical relations. Once these notions are clearly distinguished, it seems theoretically possible to derive the notion of grammatical subject/object from the interaction of thematic roles and cases. The definitions of grammatical relations also vary drastically according to different linguistic theories. From a formal syntactic point of view, identity of the underlying structural relation serves as the main criterion for defining/deriving a grammatical function. From a functional point of view, on the other hand, one can say that grammatical relations rank-order the noun phrases (NPs) in a clause on the basis of the values of a number of parameters in accordance with the NPs' overall communicative significance in the concrete utterance. Whether grammatical relations are universal is also a highly theory-dependent question, but in terms of formal syntactic structures, universal principles of grammatical relations can indeed be found, while the structural positions of grammatical functions might be subject to language-specific parameters.

The linguistic concept *grammatical relation*, or *grammatical function*, belongs to the most important concepts of syntactic theory. Grammatical relations characterize the structural relation between a clausal/verbal element and its dependent nominal element(s), in particular between a predicate and its subject, and the verb and its object(s). Consider the following examples:

1. *Peter sent a message to Mary.*
2. *My friend sent a congratulatory telegram to his boss.*

In addition to the verbal predicate *sent*, one can identify three NPs linked to the predicate by specific grammatical relations. One of the NPs (*Peter/my friend*) is the subject, the second (*a message/a congratulatory telegram*) is the direct object, while the third (*Mary/his boss*) is the indirect object. Generally speaking, NPs that realize the same grammatical relation occupy a designated position in a clause. In (1), for example, the subject precedes the verb, the direct object strictly follows the verb, while the indirect object is introduced by a preposition *to*. Each of the NPs is structurally distinct from the other two and makes unique reference to a concrete participant (or a thematic role) in the event denoted by the given sentence.

Grammatical relations are very useful in linguistic analysis. First, they permit identification of the various participants in the event (i.e., the subject is identified as the agent or actor of the sending event, the object as the theme being sent, and the indirect object as the recipient or goal of the sending event). Second, they allow us to identify possible structural transformations among sentences/constructions. For example, one can detect that (3) and (4) are both structurally and semantically related to sentence (1) because the NPs *a message* and *Mary*, which play the same thematic roles (the theme being sent and the recipient, respectively), have dislocated from the direct object and the indirect object positions to the subject position, respectively, while the optional agent NP is then introduced by a preposition *by*. Such transformations identify the signature properties of the passive construction in English:

3. *A message was sent to Mary (by Peter).*
4. *Mary was sent a message (by Peter).*

In addition to NPs with distinct thematic roles, subjects (and objects) can also be clausal, as in (5). Some languages, like English, also allow (and even require) a dummy element to occupy the subject position, like *it* and *there* (the so-called expletive subjects) in (6) and (7):

5. [***That he won***] is fine.
6. ***It*** *is fine that he won. (cf *Is fine that he won.)*
7. ***There*** *comes a strange man. (cf *Comes a strange man.)*

However, this obligatory 'subject' requirement is not seen in the so-called 'null subject languages,' such as Chinese, Japanese, Korean, Italian, Spanish, etc. The following example illustrates a Chinese sentence without an apparent subject:

8. ø zhaodao ta le.
   find he LE
   'Someone has found him.'

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52034-0

Furthermore, some languages, like Chinese and Japanese, also allow for null objects, where an apparent object is missing in a transitive predicate, as in (9):

9. Wo zhaodao ø le.
   I find LE
   'I found (it).'

What Do Grammatical Relations Mean?

Despite the widespread use of the terms subject and object, traditional grammar did not succeed in giving them coherent and precise definitions. Defining 'subjects' as the 'actors' or 'agents' of the sentences might at first blush be suitable for sentences (1) to (4), but such a definition is less transparent in (5), while the subjects in (6) and (7) clearly do not fall under a definition of this type.

In a series of investigations of the last decades (cf, for instance, the pioneering work of Keenan (1976)), it has been established that in the most elementary sentences subject NPs correlate statistically with the meanings of various autonomous semantic domains. First, subjects are linked to the semantic role properties of participants in the given situation. The subject usually encodes the agent, if there is one in the sentence. If there is no agent in the sentence, then the prime candidate for subject position is the patient. In the presence of an agent, the patient is the prime candidate for the position of direct object. Sentences with an agent and patient constitute the prototypical transitive clause with a subject and direct object. Sentences with participants in other roles are assimilated to varying extents to the structure of transitive or intransitive clauses, or use the position oblique object. The participant with the role of recipient/beneficiary usually occupies the position of indirect object.

Second, there are statistical correlations with the discourse (communicative) domain (*see* Information Structure in Linguistics). Thus, subjects often communicate known (given) information, while objects communicate new information; subjects often coincide with the focus of empathy, i.e., with that participant from whose point of view the situation is described, and with the topic (theme), while objects often coincide with the comment (rheme).

However, these distributional correlations are often probabilistic in nature, rather than deterministic, and exceptions to these generalizations can be abundant and systematic. The confusion is amplified by the fact that traditional grammar does not often distinguish different types of 'subjects' and 'objects.' Recent advances in formal syntax, however, identify at least three types of subjects: thematic subjects, case subjects, and structural/grammatical subjects, and the formal syntactic theories have rather successfully formalized the possible structural relations among them (for convenience, the discussion here is limited to subject, but similar notions may apply to objects as well). First, thematic subjects are related to thematic roles (*see* Valency and Argument Structure in Syntax), and thematic subjects, or external arguments, refer to agent/actor/experiencer roles, which are determined by the predicate as a whole (the thematic roles of X's are very different in X *killed a man* and X *killed time*, where the verb phrase as a whole determines the thematic role of X). Case subjects refer to NPs that are assigned a designated case, that is, the NP with nominative case in accusative languages (*see* Case, Morphological: Linguistics). Finally, structural/grammatical subjects refer to NPs that occur in a designated syntactic position in the hierarchical structure. Theoretically, it is possible to derive grammatical subject from the combination of thematic subject and case subject. Nevertheless, grammatical subjects are not equivalent to either thematic subjects or case subjects alone. In (6) and (7), the expletive subjects are not assigned any thematic roles. In some cases, grammatical subjects may also be caseless, such as the unpronounced grammatical subjects in infinitive clauses in English (*see* Control, Syntactic): *John tried* (*ø to fix the car*) (*ø = John*). The empty subject is a thematic subject and a grammatical subject, yet it occurs in a position that is not assigned case.

Structurally speaking, one of the distinctive properties of grammatical subject is that it occupies the most dominant position than any other arguments. For example, it has been shown that when a pronoun has a coreferring reading with (or is bound by) a universal quantified NP (*see* Quantifiers), the universal QP must be located in a structurally more dominant position than the 'bound' pronoun. Technically speaking, the universal QP must c-command the bound pronoun (*see* Generative Grammar):

10. a. everyone likes his mother. (*everyone* and *his* can co refer: x likes x's mother.)
    b. His mother likes everyone. (*everyone* and *his* cannot co refer: *x's mother likes x.)
11. a. Everyone sent a postcard to his mother. (*everyone* and *his* can co refer.)
    b. His mother sent a postcard to everyone. (*everyone* and *his* cannot co refer.)

Examples (10) and (11) show that there is an asymmetry between the structural position of subject and those of the other arguments. The subject is able to c-command the direct object and the indirect object, yet none of the arguments can c-command the subject. The subject thus occupies the most prominent structural position in the syntactic structure. The subject is also obligatory in some languages, in contrast to all other arguments (no languages impose an obligatory object requirement). Notably, there is often a unique structural position for the subject in a given language, but the exact position might vary cross-linguistically (see the section 'Grammatical Relations and the Functional Approach to Language').

How Are Grammatical Relations Encoded?

Languages may employ different means to encode grammatical relations. The best known morphological category specifically designated to encode grammatical relations is case (Morphological Case in Linguistics). Overt morphological case marking is present in many language families, e.g., in Latin, Greek, the Slavic and Dravidian languages, the Altaic languages, the languages of Australia, and many of the Austronesian languages. Under overt case marking, grammatical relations are expressed through various overt morphological forms of nouns (as in Latin and Russian) or through different forms of other structural constituents related to NPs (e.g., forms of articles and nouns in German). Alongside inflectional morphology, many languages (such as Japanese and Korean)

make use of grammatical words or particles (usually prepositions or postpositions), which combine with NPs to give rise to analytical elements that indicate grammatical relations (e.g., in English, the combination of preposition *to* and NP, such as *to Mary* in (1), encodes the indirect object). In some languages, overt morphological marking may be indicated not on NPs, but on the verb by means of agreement (*see* Grammatical Agreement): The form of the verb expresses information about the grammatical properties of that NP which stands in a particular grammatical relation to the verb (or auxiliaries). An example in English is agreement of the verb (or auxiliary) with a third-person singular subject in number. Some languages have polypersonal agreement of the verb with two or more NPs. Thus, in Abkhaz the verb has three agreement positions indicating agreement with specific syntactic types of NPs. The linear order of NPs in the sentence is the positional equivalent of inflectional or analytical marking (*see* Word Order) and is calculated according to the position of the NP relative to the verb, relative to the beginning or end of the sentence, or relative to other NPs. This strategy is often seen in languages without overt morphological case markings. Thus, in linguistic typology, it is common to characterize languages in terms of their unmarked word orders among subject, verb, and object. For example, one can distinguish between SVO languages (e.g., English and Chinese) and SOV languages (e.g., Japanese and Korean), the combination of which constitutes the largest share among world languages. It is noteworthy that the mainstream generative grammar embraces the hypothesis that case is universal in natural languages, and for those overt case markings are not observed, cases are assigned under specific structural configurations that are systematically mapped to certain linear word orders. If such a position is maintained, then the close association between word order and case assignment can be established through structural relations.

Grammatical relations are also strongly tied with grammatical voices. Take English for example. In a sentence with a transitive voice, the NP with the thematic role agent/actor emerges as the grammatical subject, while in a sentence with a passive voice, the NP with the thematic role patient/theme emerges as the grammatical subject. Some languages, especially the Austronesian languages, have other voice constructions (inflected on verbs) that allow NPs with various thematic roles (e.g., instrument, location, beneficiary, etc.) to surface as grammatical subjects.

Formal Analyses of Grammatical Relations

Modern formal theories of syntax may speak of grammatical relations directly as theoretical primitives (as in lexical function grammar and relational grammar) or indirectly as derivatives of theta roles and cases (as in generative grammar). Nevertheless, one common ground is that grammatical relations strongly correlate to verb/predicate types. Four types of predicates will be briefly introduced: accusative/transitive, unaccusative, ergative, and unergative.

A typical accusative/transitive verb takes one or two objects, in addition to the subject. An example of transitive verb is *like*, as in *He likes her*, and *send*, as in *John sent a letter to Mary*, the latter of which is called a ditransitive verb. In the former example, *he* is a nominative marked NP with an agent/actor role and occupies the structural subject position, while *her* is an unaccusative marked NP with a patient role and occupies the (direct) object position. In English, it is not possible to use expletive subject in transitive sentences (cf *there ate John some cake), but it is possible to find such sentences in Icelandic, as in (12) (from Bobaljik and Jonas, 1996: 196):

12. það borðuðu sennilega margir jólasveinar bjúgun
    there ate probably many Christmas. the.
    trolls sausages
    'Many Christmas trolls probably ate the sausages.'

Transitive sentences can also undergo passivization in which the agent NP is demoted to a less prominent position and the patient NP in turn occupies the structural subject position (and obtain the structural nominative case). Under a structural account, it is argued that, in active sentences, the agent NP is base-generated in a position closer to the grammatical subject position than the patient NP, and therefore, the agent NP is the NP that can move into the grammatical subject position, rather than the patient NP, as in (13):

13. [subject position: ___ [Agent [V Patient]]]

When a transitive verb undergoes passivization, on the other hand, the agent NP is demoted, and the verb no longer assigns an accusative case to the object position, and therefore, this forces the patient NP to move into the structural subject position instead:

14. [subject position: ___ [[V Patient] [*by* Agent]]

For unaccusative verbs, such as *arrive*, *appear*, and *come*, there are no agent arguments, and the only argument (a theme NP) may either stay in the object position or move to the subject position (for nominative case), as shown in the following examples:

15. a. There arrived three guests.
    b. Three guests arrived.

Unlike transitive predicates, the promotion of the theme argument to the subject position does not require a passive voice in this type of predicate, and an expletive may occupy the subject position. Under a structural account, the obligatory subject position is either fulfilled by an expletive *there* or triggers the theme argument to move into the subject position:

16. a. [subject position: *there* [V Theme]]
    b. [subject position: _____ [V Theme]]

In the null subject languages, where there is no obligatory subject requirement, such as Chinese, the subject can be left empty in this type of predicate:

17. a. ø Lai-le san ge keren.
    come-LE three Classifier guest
    'There came three guests.'
    b. San ge keren lai-le.
    'Three guests came.'

An ergative verb is minimally different from the transitive and the unaccusative verbs in that the agent argument is

optionally projected in the argument structure. Examples of ergative verbs in English are *roll*, *sink*, *open*, etc., as in (18) and (19). The structural configuration of ergative verb is displayed in (20):

18. a. John rolled the ball down the hill.
    b. The ball rolled down the hill.
19. a. Peter opened the door.
    b. The door opened.
20. [subject position: ___ [(Agent) [V Theme]]]

In the (a) examples, the cases assigned to the subject and the object are the same as the transitive predicates, where the subject position is assigned a nominative case and the object position an accusative case. In the (b) examples, on a par with the unaccusative predicates, the theme argument (as the only argument) must move to the subject position and is assigned a nominative case. Unlike unaccusative predicates, however, expletive subjects are not allowed in ergative predicates in English: **There rolled a ball down the hill*. Therefore, when the agent role does not appear, movement of theme NP to the subject position is obligatory. It has also been argued that the agent argument in this type of predicate is introduced by a silent causative verb, and therefore, in (18a) and (19a), the structures may involve an additional layer of null verb CAUSE:

21. [subject position: ___ [Agent/Causer CAUSE [V Theme/Causee]]]

Finally, an unergative verb, like *laugh*, *complain*, *lie*, etc., can only project an agent argument, which, being the only argument, moves to the subject position and is assigned a nominative case. There is no direct object in this type of predicate. However, an indirect object may appear if it is introduced by a preposition, as shown in (22). Formally, this type of predicate has the structural configuration in (23), where the only argument (the agent NP) ultimately moves into the subject position:

22. a. Tom laughed (at the girl).
    b. Harry complained (about his lunch).
23. [subject position: ____ [Agent V]]

It is therefore possible for the formal structural analyses to derive the less transparent notions of grammatical relations from more primitive and well-defined notions of theta roles (which are regulated by argument structures) and cases, and thus avoid the ambiguous uses of grammatical relations.

(Non)universality of Grammatical Relations

Whether grammatical relation is universal is a theory-internal question, and answers to the question vary according to different theoretical assumptions and syntactic tests. In descriptive linguistics and linguistic typology, where linear word orders and functional morphosyntactic alignments are concerned, one usually concludes that grammatical relations are not universal among languages, and some languages might even have no well-defined grammatical relations at all. The widely adopted morphosyntactic alignment test is often carried out by nuclear arguments with the symbols S, A, P (or O), where S is the nuclear argument of an intransitive clause, and A and P the agent-like and patient-like arguments, respectively, of a transitive clause, then in European languages the S/A arguments have identical encoding, grouping them together as the grammatical relation of subject, in opposition to the encoding of the P argument. Such a system is called accusative alignment. Alongside this possibility, many languages found in various continents have the ergative pattern (e.g., Basque, Dyirbal), uniting the S/P arguments in opposition to the A argument. Here the S/P arguments are usually morphologically unmarked, while the A argument is marked (ergative case or its analog). Examples (24) and (25) draw a comparison between an accusative language like Japanese and Dyirbal (from Aldridge 2008):

24. Japanese (NOM = Nominative, ACC = Accusative)
    a. Hanako-ga kita.
       Hanako-NOM came
       'Hanako came.'
    b. Hanako-ga Taro-o hihan-sita.
       Hanako-NOM Taro-ACC criticize-did
       'Hanako criticized Taro.'
25. Dyirbal (ABS = Absolutive, ERG = Ergative, NF = Nonfuture)
    a. yabu banaga-n^{y}u
       mother.ABS return-NF
       'Mother returned.'
    b. nguma yabu-nggu bura-n
       father.ABS mother-ERG see-NF
       'Mother saw father.'

The ergative alignment of nuclear arguments thus brings about an analytical challenge for theories of grammatical relations. Other patterns are also found in natural languages. One possibility is a pattern that distinguishes agent-like and patient-like arguments of both transitive and intransitive clauses (active alignment). Under active alignment one finds different expression of the single argument of verbs like 'run' and verbs like 'fall.' There is even the tripartite scheme, distinguishing all three arguments, S, A, and P. Finally, there is the neutral pattern, which fails to differentiate the S/A/P arguments by means of coding. Language of this type is often claimed to have no grammatical relations at all (Dixon, 1994; Van Valin and LaPolla, 1997).

From a structural point of view, on the other hand, where more complicated hierarchical relations and structural dependencies are taken into consideration, grammatical relations are generally considered to be universal and may be derived from more primitive and universal notions like theta roles and cases, as illustrated in the section 'Formal Analyses of Grammatical Relations.' For example, the universal principle of subjecthood is that the structural position of subject is structurally more prominent than all other argument positions, and a language always has a designated structural position for grammatical subject that is derivationally related to thematic and/or case subjects. While the principle holds, languages may still differ with respect to the structural position where a given grammatical relation is encoded. For example, it is often argued that the grammatical subject in English occupies a unique position licensed by the inflection or tense phrase (or the specifier of TP), which dominates the verb phrase (VP), while the object NP is base-generated as a complement or specifier of verb inside VP. On the other hand, it has been argued that the grammatical subject in Irish occupies a lower position (perhaps inside the VP) than

that in English. McCloskey (1996, et seq.), for example, has demonstrated that in Irish, the subject is elided along with the object in the VP-ellipsis construction:

26. Ní tháinig muid 'na bhaile anuraidh
not came we home last-year
ach tiocfaidh — i mbliana
but come [Future] this-year
'We did not come home last year, but we will
(~~come home~~) this year.'

Irish is a language with the VSO word order, where the verb is argued to move to a higher position out of VP (to the tense or inflection) and pass the structural position of subject. If the subject in Irish also moved out of VP to a position licensed by tense/inflection phrase (like the subject in English), we would expect that after VP-ellipsis, the subject should escape being elided within the VP. The fact that subject and object are both elided in the VP-ellipsis construction in Irish then suggests that the Irish subject occupies a position inside VP, on a par with the object. Conversely, in some Austronesian languages, it is often argued that the grammatical subject may occupy a structurally higher position than that in English. For example, Pearson (2005) has argued that the grammatical subject in Malagasy occupies a position typically associated with topic and *wh*-movement (*see* Movement Theory and Constraints in Syntax), which is a higher projection than TP. In this type of language, the structural requirements of topics outweigh those of grammatical subjects to an extent that the role of topic has replaced the grammatical function of subject. In language typology, languages of the Malagasy type are generally referred to as topic-prominent languages, in contrast to subject-prominent languages, such as English and French. Some languages, such as Japanese and Korean, show mixed characteristics, where subjects and topics may coexist and are both considered prominent in their discourse functions.

The controversial issue of ergative alignment, which is often used as an argument against the universality of grammatical relation, may also be neutralized once a more articulated structural account is adopted, especially when we consider grammatical relations as derivatives of theta roles and case assignments. Recent studies in Legate (2002, et seq.) and Aldridge (2004, et seq.), for example, both argue on independent grounds that the ergative case in ergative languages is tied to the thematic role of agent/actor (or the external argument), and the absolutive case is identified as the default unvarying form of structural cases (compared to nominative case and accusative case in accusative languages). If such approaches are on the right track, then the difference between ergative languages and accusative languages simply supports the idea that grammatical relations are not primitives in natural languages, but are derivatives of universal notions of theta roles and cases, as argued in the mainstream generative grammar (Williams, 1984).

Grammatical Relations and the Functional Approach to Language

The functional explanation of grammar (*see* Functional Approaches to Grammar) has permitted establishing the polyfunctional character of the elementary categories that form the clusters known as grammatical relations. The majority of these categories were themselves discovered and investigated in the framework of the functional approach (Kibrik, 1997).

In this connection, the question of the existence of different patterns of encoding S, A, and P arguments merits special attention. Proceeding from the now widely established assumption of the iconicity of the linguistic sign (*see* Iconicity in Linguistics), replacing the Saussurean assumption of the arbitrariness of the sign, one can allow for the existence of a functional motivation for the various coding patterns. These patterns unite arguments with different elementary roles in different ways. The basic prototypes of all these groupings (*see* Linguistics: Prototype Theory) are given by the agent and patient of the transitive construction. From this viewpoint, active alignment is a natural metonymic extension of the elementary roles of agent and patient, generalizing them to the hyperroles (macroroles) of actor (the participant in the event that performs, effects, instigates, or controls it) and undergoer (the participant in the event that does not perform, effect, instigate, or control it, but rather is affected by it in some way). Arguments with different elementary roles can be interpreted in terms of these hyperroles.

Accusative alignment is also motivated essentially not by grammatical relations, but by the hyperroles principal and patientive. The principal indicates the main participant, the 'hero' of the situation, who is primarily responsible for the fact that this situation takes place. In the transitive clause the principal is, of course, the agent-like argument, while in the intransitive clause the single nuclear argument has no competitors for the role of principal. The patientive is the most patient-like participant of a multiparticipant event. This role unites, in addition to the patient, arguments of other types.

Ergative alignment articulates the S, A, P arguments by means of other hyperroles, absolutive and agentive. The absolutive is the metonymic extension of the patient to intransitive verbs; it is the immediate, nearest, most involved, or affected participant in the situation. In the transitive clause the patient is most involved in the situation. In the intransitive clause there is no competition for the role of the closest and most involved participant in the situation. The absolutive in the transitive clause is in opposition to the agentive, the most agent-like participant of the multiparticipant event.

Tripartite alignment distinguishes agentive and patientive of the transitive clause, distinguishing them from the single nuclear argument of the intransitive clause.

All these means of generalizing the elementary roles are in principle motivated, but a language has the option of grammaticalizing just one of them as its basic pattern. In addition, a language may have different patterns in different contexts, and examples of this kind have been attested.

Grammatical Relations and the Cognitive Approach to Language

The 'statistical' correlations between concepts of different semantic domains noted above and which are grammaticalized in grammatical relations and the means of their encoding are not chance, rather they have a cognitive nature, reflecting

the human capacity for categorizing reality. Behind the limitless variety of whole grammatical systems lie the same stable cognitive structures of human thought and the pragmatic strategies (*see* Pragmatics, Linguistic) for their verbalization. The reconstruction of these structures and strategies on the basis of data from different languages is the task of cognitive typology (*see* Linguistic Typology).

Grammaticalization

Paolo Ramat, Center for Postgraduate Education and Research LETiSS, Istituto Universitario di Studi Superiori (IUSS) (Retired), Pavia, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

What do we mean by 'grammaticalization'? What are the criteria for establishing grammaticalization processes? After a short sketch of the past debate some 'canonical' examples of grammaticalization are discussed in this article. One of the main points in today's discussion concerns the nature and the causes of grammaticalization process: does it happen step by step along a continuum or is it an abrupt innovation? Examples are discussed and evidence is adduced in favor of the former alternative: there exists a diachronic dynamic of the grammaticalization processes, but at the end of a process we may have an abrupt transcategorization. Finally, this article discusses the much debated question of the unidirectionality of the grammaticalization phenomenon and concludes that grammaticalization and degrammaticalization (with lexicalization as possible output) are two complementary processes along a continuum which move into two opposite directions. Thereby, reanalysis plays an important role in the shifting from grammar to lexicon and vice versa.

Definition of Grammaticalization

Many definitions of grammaticalization have been suggested according to various theoretical approaches. One of the most diffused and clearest is Kuryłowicz' definition: "Grammaticalization consists in the increase of the range of a morpheme advancing from a lexical to a grammatical or from a less grammatical to a more grammatical status," Kuryłowicz (1975). Some examples of grammaticalization are Latin *habere* from a full verb meaning 'to grasp, seize' developed to an auxiliary in periphrastic verbal constructions for the expression of the future (*dicere habet* 'he/she has to say > shall say') or the past (*dictum habet* 'he/she has said'). The prepositional + relative phrase of the Old English *þa hwile þe* 'at the time that' evolved to the adversative and even concessive meaning of the Modern English conjunction *while* (see Traugott and König, 1991). The Latin demonstrative *ille* 'that,' with strong deictic function (:*ille homo* 'that man,' *homo ille* 'that notorious, famous man') gave rise to the obligatory article of the Romance languages (French *l'homme*, Spanish *el hombre*), where its function is simply to mark the noun phrase as determined (vs *un homme*, *un hombre*, indefinite). Grammaticalization is thus a process leading from lexemes to grammatical formatives: "a sign is grammaticalized to the extent that it is devoid of concrete lexical meaning and takes part in obligatory grammatical rules" (Lehmann, 1995: p. 6).

Sometimes the terms 'grammaticization' or 'grammatization' have been used instead of grammaticalization without any substantial difference.

As is shown by the example of Latin *ille*, grammaticalization may lead to the emergence of new grammatical categories (in the case in point, the article which did not exist in Latin). In all the adduced examples the grammatical output of the process has passed through a syntactic use of the lexeme: see the evolution path below. Note, however, that not all the steps of the path need be always present.

Lehmann (1995: p. 123) has suggested three relevant aspects of grammaticalization, which realize six parameters both at the paradigmatic and syntagmatic level (see **Table 1**).

While grammaticalization is a process, the six parameters are not processes but properties that linguistic forms possess in increasing or decreasing measure. A linguistic form shows integrity inasmuch as it maintains its phonological and semantic identity. Phonological erosion and semantic bleaching reduce the integrity of a form (Latin *ille* > Italian *il*, Spanish *el*, etc.). The scope is the structural size (the 'weight' in Lehmann's terms) of a construction: when a full verb is grammaticalized as auxiliary it makes up one phrase with the main verb and thereby reduces its scope to just the main verb (see the example of *habeo cultellum inventum* 'I have found a knife' in Section The Continuum of the Grammaticalization Process). By paradigmatic cohesion is meant the formal and semantic integration of a form into a paradigm: the suppletive forms *better*, *best* are less paradigm-integrated than *longer*, *longest*. Bondedness refers to the syntagmatic cohesion: the more a form is grammaticalized the more it will be syntagmatically constrained; French *le*, Spanish *el*, etc. are fully grammaticalized noun determiners which cannot appear in isolation. Paradigmatic variability refers, according to Lehmann, to the freedom with which the language user chooses a sign – and, again, variability decreases with increasing grammaticalization: for instance, if cases are weakly grammaticalized the case suffixes may vary with relative freedom:

(1) Hungarian

a gyerek az asztal-on	*jatszik*
The child the table-SUPERESSIVE	plays
'the child is playing on the table'	

but *asztal-nál* (ADESSIVE) and *asztallal* (<*asztal-val*, INSTRUMENTAL-COMITATIVE) would also be possible,

Table 1 Six aspects of grammaticalization

	Paradigmatic level	*Syntagmatic level*
Weight	Integrity	Scope
Cohesion	Paradigmaticity	Bondedness
Variability	Paradigmatic variability	Syntagmatic variability

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53011-6

while keeping the same meaning. Another example of paradigmatic variability is as follows: the use of Latin *ille* was not compulsory in pre- or postnominal position and was semantically governed, but in Romance languages it is in most cases impossible to have a noun without the article. Finally, the syntagmatic variability is the ease with which a form may be shifted in the linear order of a sentence: the more a form has undergone a grammaticalization process the less variable it will be; **I have a knife found* or **I have a found knife* are impossible in Modern English, and the only grammatical form is *I have found a knife*.

It has to be noticed that the processes alluded to under the three labels of weight, cohesion, and variability cut across different levels of language structure; therefore the same items (e.g., *ille*) turn out to be appropriate examples of different parameters (integrity, scope, etc.). Grammaticalization is a pervasive phenomenon whose effects may be seen at all linguistic levels. Consequently, "There is a growing interest in integrating grammaticalization with theoretical work in descriptive and historical linguistics" (Giacalone Ramat and Hopper, 1998: p. 1).

A Historical Sketch of the Research

The classical examples of *dicere habet* and *l'homme* go back to Antoine Meillet (1916, repr. 1948), who probably used first the term grammaticalization – though the concept is implicitly referred to by some previous linguists such as Wilhelm von Humboldt (*Über das Entstehen der grammatischen Formen und Ihren Einfluß auf die Ideenentwicklung* (On the Origin of Grammatical Forms and their Influence on the Ideas' Development), 1825), William Dwight Whitney (*The Life and Growth of Language: An Outline of Linguistic Science*, 1875), Georg von der Gabelentz (*Die Sprachwissenschaft: Ihre Aufgaben, Methoden und bisherigen Ergebnisse* (Linguistics. Its tasks, methods, and up to now results), 1901), and others (see Lehmann, 1995: Chapter 1; Heine et al., 1991: pp. 5–11).

As can be seen from the titles just quoted, grammaticalization has from the very beginning been considered in a large theoretical frame as one of the most characteristic developments languages may undergo. This holds also for the linguists of the following generations. Edward Sapir (1921: p. 102), for one, observed that "it is possible for a concrete concept, represented by a simple word, to lose its material significance entirely and pass over directly into the relational sphere [i.e., the expression of abstract morphosyntactic relations, PR] without at the same time losing its independence as a word": forms live longer than their own conceptual content, which may be bleached (weakened) and eventually fade completely. Sapir's examples are the Chinese and Cambodian verbs for 'give' used in a very abstract sense to express the 'indirect object' relation (see also Section The Present State of the Discussion about Grammaticalization).

Though not using the term grammaticalization, the French linguist Emile Benveniste (1968) took up again the case of *habere*, and called it a conservative mutation whereby a new (periphrastic) form takes over the function of an older one in the grammatical paradigm (e.g., *habeo dictum* 'I have said' instead of *dixi* 'I said').

In the last 30 years or so grammaticalization studies have experienced a real boom, as part of a countermovement to the dominant formal approaches to linguistics (though generative research has also contributed to the study of grammaticalization) (e.g., Roberts and Roussou, 2003; van Gelderen, 2004; Batllori et al., 2005). After the pioneering studies by Givón (1979), Hopper (1987), Traugott and Heine (1991), Heine et al. (1991), Bybee et al. (1994), Lehmann (1982, repr. 1995), a real flood of monographies and articles was published. A critical assessment of grammaticalization was edited by Campbell in a special issue of 'Language Sciences,' 2001.

An important point in Campbell's contribution to the special issue is the question whether grammaticalization can be considered as a theory per se. Campbell's answer is 'No.' He argues that "grammaticalization does not have any independent status of its own, but rather is derivative of other kinds of language change" (p. 116). However, this epistemological question needs to be further discussed (cf Newmeyer, 1998; Fischer, 2000; among others).

In the mentioned special issue the introductory paper by Campbell and Janda gives an exhaustive review of the many definitions that have been given of 'grammaticalization' (Campbell and Janda, 2001). A new book series called 'New reflections on grammaticalization,' which collects the proceedings of international conferences with the same title, started in 2002. The fifth and most recent conference took place in Edinburgh, in July 2012. Reasons of space do not permit to provide here an exhaustive bibliography of the works on grammaticalization that deal with general as well as particular aspects of the phenomenon. Just to give an idea of the breadth of topics which go under the label 'grammaticalization' we can mention van Gelderen (2004) on grammaticalization as economy or Heine and Kuteva (2005) on contact-induced grammaticalization, and, among the most recent writings, Traugott and Trousdale (2010) on synchronic gradience and grammaticalization and Heine and Kyung-An Song (2011) on the grammaticalization of personal pronouns. Stathi et al. (2010) offer a panorama on current views and issues of grammaticalization. A short list of further readings, not directly quoted in text, has been added to the references.

As happens when terms become fashionable, the original meaning of 'Grammaticalization' – as results in Kuryłowicz' definition given at the beginning of this article – has been extended (and therefore bleached) to cover practically almost any phenomenon of language change. On (previous) research on grammaticalization from a broader perspective see Bisang et al's. 2004 book on grammaticalization which has the significant subtitle 'A look from the fringes and its components.' Heine and Kuteva have published a lexicon of grammaticalization as a reference book in an attempt to collect data from as many different languages as possible (Heine and Kuteva, 2002): they have listed more than 400 grammaticalization processes that may have resulted in new grammatical forms; see for instance, German *rings*, genitive of the noun *ring* 'ring' → preposition as in *rings um den Dom* 'round about the cathedral,' exactly as in Icelandic *í kring um húsin* 'around the houses' (lit. in the circle around the houses), or Latin *Terra se conuertit circum axem suum* 'the earth turns around its own axle,' where the preposition *circum* is actually the accusative of the noun *circus* 'circle' (Heine and Kuteva, 2002: pp. 67f).

Indefinite pronouns can originate from nouns meaning 'person, man' as in Albanian

(2) *s' pashë njeri*
NEG I saw someone$_{ACC}$ 'I haven't seen anybody,'
or in French
(3) *on parle français*
'French is spoken,'

where *njer* in (2) means 'man' and *on* in (3) derives from Lat. *homo* 'man.' The shift from the original nominal meaning to the impersonal pronoun did not happen suddenly: there are so-called bridging texts where both interpretations – noun and/or pronoun – are possible. The famous 'Oaths of Strasbourg' (842) have in the Romance version

(4) *si cum* ***om*** *per dreit son fradra salvar dift*
as man with right his brother save must
'as a man rightfully must save his own brother,' or 'as one rightfully' etc.,

The German version has

(5) *sōso* ***man*** *mit rehtu sīnan bruodher scal (scil. haldan)*
as man with right his brother must (save, protect).

Present-day German has kept the double meaning of *man*:

(6) *Ich habe einen* ***Mann*** *gesehen* 'I have seen a man' and
(7) ***Man*** (weakened form of Mann) *spricht Deutsch* 'German is spoken,'

whereas French distinguishes between *homme* 'man' (from the Latin accusative form *homine(m)*: see below) and *on* '(some) one.' We can say that French went a step further in the grammaticalization process of the original Lat. *homo* in that *on* keeps no trace whatsoever of its origin.

Recently, Narrog and Heine have edited a very large and comprehensive handbook of grammaticalization in the series 'The Oxford Handbooks in Linguistics' (Narrog and Heine, 2011).

The Present State of the Discussion about Grammaticalization

The Continuum of the Grammaticalization Process

Already Whitney and Benveniste had underlined the fact that linguistic changes do not happen abruptly: "Present possession often implies past action: *habeo cultellum inventum*, (…) *habeo digitum vulneratum* 'I possess my knife' (recovered after loss) [>'I have found the/my/a knife,' PR], (…) 'I have a finger wounded' [>'I have wounded my finger,' PR]." Thus, *I have found the knife* became the indicator of "a peculiar variety of past action contemplated as completed," (Whitney 1875: p. 91; cf Heine et al., 1991: pp. 7f). Benveniste gives an insightful philological description of how the periphrastic forms with *habere* came first to be used and later spread out.

As a matter of fact, grammaticalization, like all terms ending in *–ization*, alludes to a gradual process, not a state. Grammaticalization is different from grammar. Even what has recently been alluded to as 'synchronic grammaticalization' implies a process whose final stage cannot be simultaneous with the beginning moment. Grammaticalization occurs in gradual microsteps, as we have seen when speaking of 'bridging texts' with the example from the 'Oaths of Strasbourg' (see further the Ewe examples (10)–(12), below). This is not in keeping with the assumption by generative transformational grammar of rigidly separated grammatical categories: clines, continua, squishes are by definition ruled out. When generativists try to take account of the microsteps, they are bound to a proliferation of discrete grammatical categories (cf Vincent and Börjars, 2010). Actually, the 'new trend' of grammaticalization studies which has flourished in linguistics since the 1980s is basically oriented toward a functionalist approach, with very few exceptions. Grammatical categories are not seen as waterproof boxes; they permit, on the contrary, the gradual leaking of forms from one category to another. Just to give an example, the German particle *auch* 'also, too, even' was originally an imperative of a verb meaning 'add' (cf Lat. *augeo* 'augment'). The next paragraph discusses a classical case of transcategorization (on the term 'transcategorization' see below in this section). It may also happen that a grammaticalization process is interrupted and, so to say, reversed. Old Italian knew *(u)omo* as indefinite/impersonal pronoun:

(8) *co(n) ciò sia cosa che Dio sia inn o(n)gna luogo, inn ogna luogo può* ***l'uomo*** *servire Dio*
(Anonymous, *Trattati di Albertario da Brescia volgarizzati*, IV, 23: 1288).
since God is everywhere, man/one can serve God everywhere (cf Giacalone Ramat and Sansò, 2007).

Present-day Italian does not know this use of *uomo* any longer and *uomo* means simply 'man, person.' We can represent this interruption of the grammaticalization process as follows.

(9) A > A,B > A

where A represents the original phase (i.e., *(u)omo* meaning just 'man'), A,B the intermediate phase with the coexistence and a possible contrast between the A and B (=impersonal pronoun) meanings, and, finally, the come back to A and the disappearance of B which was substituted by another form (namely *si*, as impersonal pronoun). In a complete grammaticalization the third step would be B (i.e., A > A,B > B) as in French *on*, where A disappears and is substituted by another form (namely *homme* < Lat. accusative *hominem*). Remember also that Middle English knew a pronoun *man*, just as Germ. *man*, until the fifteenth century. But later this indefinite pronoun was abandoned.

To be functionally oriented in grammaticalization studies means that large attention is paid to the internal mechanisms, that govern linguistic structures, and the external psychological/cognitive causes of grammaticalization. Several linguists have hinted at the fact that grammaticalization very often originates in discourse strategies (i.e., in pragmatics), evolving to syntactic structures, and later obligatory morphological markers (up to a possible total erosion of the markers) along the cline:

Discourse > Syntax > Morphology > Morphophonemics > Zero (see Givón, 1979: p. 209, 2009; cf Lehmann, 1995: p. 13; Traugott and Heine, 1991: p. 3, Bybee et al., 1994: pp. 40f). A good example of this evolution is the so-called Jespersen's cycle (Jespersen, 1917) of the negative construction in French, and other languages. First, we had constructions as Lat. *Non uado passum* 'I don't go a step,' where *passum* (step$_{ACC}$)

is used as the object of the intrinsically intransitive verb 'to go' and the negation is expressed by *non*. The sentence has a strong emphasis at the discourse level, like *non comedo/manduco mica(m)* 'I don't eat a crumb,' *non bibo gutta(m)* 'I don't drink a drop,' etc. Thereafter, *pas(sum)*, *mica(m)*, *gutta(m)* became Negative Polarity Items (NPIs) that denoted a least quantity and were used, like *pas*, to reinforce the negation. Thus, we get the syntactic construction with double negation *je ne vais pas*. But, because of its semantic bleaching, *pas* turned out to a plain negation marker (even ousting other NPIs: (Old) French *mie* < Lat. *mica(m)* 'crumb,' *gote* (French *goutte*) < Lat. *gutta(m)* 'drop,' etc.) so that it became possible to say *je ne vois pas* 'I don't see,' *je ne comprends pas* 'I don't understand,' etc.: *pas* lost its original meaning ('step') and was used just as a marker of negation. Modern spoken/colloquial French has *je vois pas*, *je comprends pas* where *pas* is the only morphological negation marker and the first member of the double negation, i.e., *ne*, has been dropped to zero. Finally, in French-based creoles we may find *mo pa kup* (Louisiana, from French **moi pas coupe*) 'I don't cut,' *nu pavle* (Guadeloupe, from French **nous pas voulez*) 'We don't want' where *pa* (<French *pas*) is again in preverbal position as was *non* at the beginning of the cycle, since in the discourse strategy the verb is usually in the scope of the negation (cf Condoravdi and Kiparsky, 2005; Ramat, 2006).

The Latin example *habeo cultellum inventum* discussed above also originates at the discourse level: the speaker wants to underline that he does really possess (*habet*) a knife which has previously been found (*inventum*) and uses a construct where every word keeps its own value. This pragmatic, effect-loaded expression evolves to a standard analytic construction of the syntax (with inversion and no longer with syntagmatic variability (see Section Definition of Grammaticalization above): *habeo inventum cultellum*) and finally enters the morphological paradigm of the verb *invenire* 'to find' as its periphrastic past form (note that at this stage of the Romance languages it is no longer possible to have the word order *habeo cultellum inventum* (**j'ai le couteau trouvé*): the auxiliary has agglutinated to the main verb and no other word can be inserted between the auxiliary and the main verb). As an example of morphophonemic evolution one can quote the French future *dir-ai*, *dir-a*, etc. 'I shall say,' '(s)he shall say' or Catalan *cantaré*, *cantarà*, etc., from periphrastic future forms with *habeo*: *dicere habeo*, *dicere habet* and *cantare habeo*, *cantare habet*, respectively: the auxiliary has undergone phonetic attrition and has become an inflectional ending. Only in Portuguese it is possible to insert a pronoun in future and conditional forms: *comprá-lo-á* '(s)he will buy it,' *lavar-me-ei* 'I shall wash myself' and *lavar-se-iam* 'they would wash themselves,' along with the nowadays more usual *ela o comprará*, *me lavarei*, *se lavariam*.

As in the case of indefinite pronouns presented above, there is a continuum between the phases of the grammaticalization process: Heine et al. (1991: p. 1) quote the case of Ewe (Kwa branch of the Niger–Congo family):

(10) *me-ná ga kofí*
1Sg-give money Kofi
'I gave Kofi money.'

(11) *me-ple βɔtrú ná kofí*
1Sg-buy door give Kofi
a. 'I bought a door and gave it to Kofi.'
b. 'I bought a door for Kofi.'

(12) *me-wɔ dɔ́ vévié ná dodókpɔ́ lá*
1SG-do work hard give exam DEF
'I worked hard for the exam.'

In (10) *ná* has the function of a full verb, meaning 'give'; in (12) *ná* can be interpreted only as a preposition ('for'), whereas in (11) it is ambiguous and allows two different readings. Should one day the Ewe language admit for (11) only the second reading, then we would have a categorial shift (verb > preposition), much in the sense of the evolution of Old English *hwil* 'time' (noun) to *while* (conjunction) (see above, Section Definition of Grammaticalization). At the end of an uninterrupted process there is really a break and a category shift.

Shifts like verb > preposition, noun > conjunction are examples of so-called *transcategorization*. Items belonging to a main (and open) category (verb, noun) pass to a functional (and restricted) category (e.g., adposition, pre- or postposition according to the structure of the language in question, conjunction). These examples clearly hint at a move from a less grammatical to a more grammatical categorial status – it is however clear that the term *transcategorization* (or *recategorization*) is more appropriate than *decategor(ial)ization* used by Hopper (1991: pp. 30f) and others, since the word (e.g., Ewe *ná*) does not fall out of the language categories, but simply passes from one category to another (cf Ježek and Ramat, 2009).

The Dynamic of the Grammaticalization Processes

In such a dynamic typology of grammaticalization it is possible to account also for interrupted grammaticalization processes: in Old Italian it was possible to use movement verbs (*andare* 'go' and *venire* 'come') as auxiliaries in far more cases than in Modern Italian (cf Giacalone Ramat and Hopper, 1998: pp. 2f, with further references). Further, Hopper has drawn attention to what he calls 'emergent grammar,' i.e., to the incipient stages of grammaticalization at the level of discourse. As already shown in the previous section, the negative French adverb *pas* meant originally 'step'; therefore it was used first with movement verbs ('he does not go a step'), but later it spread to verbs such as 'eat,' 'see,' etc. and became, via analogical extension (cf Hopper and Traugott, 2003: pp. 65f), the general mark of negation (specialization principle). Thereby the original meaning of *pas* was completely lost (bleaching process).

As noted by Hopper himself, the principles he suggests (specialization, persistence, divergence, etc.) characterize linguistic change in general and are not distinctive for grammaticalization (Hopper, 1991: p. 21). This has raised the problem of defining the limits of grammaticalization versus other dynamic linguistic processes (cf Giacalone Ramat and Hopper, 1998).

Unidirectionality of Grammaticalization?

Unidirectionality is a much debated question in the literature on grammaticalization. If we define grammaticalization as the

process by which an item or a construction enter the grammar, unidirectionality is true by definition: it is a definitional property (cf Campbell, 2001: pp. 126f). In fact, many linguists maintain that the evolution toward grammar cannot be reversed, and there are no examples of degrammaticalization of forms that belong to the grammatical array of a language (Lehmann, 1995: p. 19; Traugott and Heine, 1991: pp. 4f; Heine et al., 1991: pp. 31f; Haspelmath, 1999, 2004; among others). This is true if by this it is meant that once a lexeme has entered the grammar, it will hardly come back and assume again a lexical value. But there are many instances of items or morphemes leaving the realm of grammar and assuming an autonomous value as lexical entries: Hungarian, Spanish, French, Italian, and many other languages have a large number of present participles used as nouns, e.g., Hungarian *költő* 'poet' (<*költ* 'to compose'), *hallgató* 'student' (<*hallgat* 'to listen to'), Spanish and Italian *cantante* 'singer' (<*cantar(e)* 'to sing'), calmante 'painkiller' (<*calmar(e)* 'to soothe'), French *revenant* 'ghost, spirit' (<*revenir* 'to come back'); nobody would recognize in French *seigneur* (>English *sir*) the accusative form (*seniorem*) of the comparative of Lat. *senex* 'old,' or in English *elder* 'official in the Presbyterian church' a comparative from Old English *ald* 'old.' Both were originally forms belonging to the grammatical paradigm of the adjectives, but later they developed an autonomous lexical meaning. Even syntactic constructs may develop to new lexemes: Dutch *misschien* 'perhaps,' (<(*het*) *mach schien* literally 'it may happen'), Italian *forse* 'perhaps' (<Latin *fors sit* (*an*) literally 'chance be (or)'), English *perhaps* literally 'per chances (plural).' Grammaticalization and lexicalization are two complementary processes (Ramat 1992; Moreno Cabrera 1998; Croft, 2003: pp. 64f), in his functional typology approach speaks of 'competing motivations.'

In Norde's words (2009: p. 120) degrammaticalization can be defined as follows: "Degrammaticalization is a composite change whereby a gram [i.e., a grammatical morpheme, or a construction: P.R.] in a specific context gains in autonomy or substance on more than one linguistic level (semantics, morphology, syntax, or phonology)." Some examples of degrammaticalized forms such as French *seigneur*, Engl. *elder*, have already been adduced above. Degrammaticalization processes are certainly less frequent than grammaticalization processes, but they exist and have to be explained. The causes for their existence are to be sought in the overall tendency to use labels as economic symbols, e.g., suffix morphemes like *ade* (from *orangeade*, *lemonade*, or even *gatorade*) can be separately manipulated and become autonomous lexemes: the label *ade* with the general meaning of 'fruit juice' is more economic than the phrase *fruit juice*, though not as transparent (see *bus*, in *school bus*, *autobus*, etc., as hypernym for 'public transportation vehicle' derived from *omnibus* 'transport vehicle for everyone'). As for constructions becoming degrammaticalized items, we can quote Lithuanian *gal* 'perhaps' along with *galbut* lit. '(it) may be' and Polish *może* lit. '(it) can' compared with Rus. *mozet* '*byt*' '(it) may be': *gal* and *może* are autonomous words meaning 'perhaps,' i.e., instances of grammatical forms which entered the lexicon as independent items. They are shortenings of small syntactic clauses (cf Ramat, 2001). Economic symbolism and noneconomic iconism which tend toward transparency are conflicting forces that are at work in every natural human language (cf Ramat, 1992: p. 557; Newmeyer, 1994: p. 69). If we had just unidirectional evolution toward grammar we would expect that languages become more and more grammaticalized, which by all evidence is not the case (see Moreno Cabrera, 1998: p. 224). On the contrary, we have a double evolution toward grammar as well as toward lexicon (see Kuryłowicz, 1975).

Phonogenesis is also a process which shows that loss of grammatical function may give rise to new lexemes (cf Hopper 1991, 1992). As the German grammatical prefix *ge-*, used to indicate collectives (see *Ge-beine* 'limbs,' plural, *Ge-dränge* 'crowd'), was no longer felt as a prefix, it underwent phonetic erosion to *g-* and gave rise to nouns such as *Glück* 'luck,' *Glied* 'limb,' *Gnade* 'grace' which synchronically are no longer analyzable: this degrammaticalized *g*-became phonetic junk, no longer recognizable as a functional morpheme, and produced new lexemes. In the same vein of reasoning we have to consider also remnants of disappeared paradigms: this applies to isolated dual forms which survived the loss of the dual declension: cf Latin *ambō* 'both' (perhaps also *octō* 'eight') with the old dual marker – *ō* we find in other ancient Indo-European languages (cf Greek *oktṓ*. But in ancient Greek the dual is still part both of the nominal and verbal flection: see *lykō* 'two wolves,' *nṓ* 'we two, the both of us,' *phileîton* 'you two/they two love').

Summing up, we may represent (see **Table 2**) the grammaticalization and degrammaticalization processes along a continuum which move into two opposite directions. At both poles of the scale we have – at the α as well at the β level – either clear lexemes (full words like *habet, perhaps*) or morphemes (inflectional – *á*, Italian and Catalan 3Sg. Fut., or Engl. – *ade* as derivational suffix). Since it is difficult to state when *habet* was delexicalized and the construct *dicere habet* became the norm to express the future, or *ade* was reanalyzed as a second member of a nominal compound, the forms *di(ce)re (h)a(be)t* and *lemon-ade* represent in the previous scheme the gradualness of the transition and are placed midway between (de)lexicalization and (de)morphologization. Transcategorization is a gradual process along a continuum, but its final output represents a break in the categorial status of the input (see Section The Continuum of the Grammaticalization Process).

In recent years the debate concerning grammaticalization has focused on the mechanisms which take part in the process: the role of metaphor and metonymy on the one hand and the role of reanalysis versus analogy on the other, have been particularly stressed: [*habeo*]$_{VB}$ [*inventum cultellum*]$_{NP}$ lit. 'I possess a found knife' was reanalyzed as [*habeo inventum*]$_{VP}$ [*cultellum*]$_{N}$ 'I have found a knife.' Analogical extension has

Table 2 The grammaticalization–degrammaticalization continuum; α represents the evolution toward grammar (grammaticalization) and β the opposite process of degrammaticalization

α.	lexicon ⟶	delexicalization ⟶	morphologization ⟶	morphology
	full words:			full morphemes:
	habet	*di(ce)re (h)a(be)t*		*dir-a*
β.	lexicon ⟵	lexicalization ⟵	demorphologization ⟵	morphology
	full words:			full morphemes:
	ade	*lemon-ade*		*– ade* (*lemon + ade*)
	perhaps			*per* (*+ haps*)

been exemplified above by the case of French *pas,* originally just an NPI, applying only to movement verbs. As for metaphors, a classical example is the English phrase *be going to* as a grammaticalized expression of future, while metonymy refers to semantic changes through contiguity. Hopper and Traugott (2003: pp. 90f) consider the evolution of the already quoted (Section Definition of Grammaticalization) Old English phrase *þa*$_{DAT}$ *hwile*$_{DAT}$ *þe* lit. 'at that time that' to the Modern Engl. conjunction *while* as a metonymical process conveyed by conversational inferences.

Grandparent–Grandchild Relationships

Teun Geurts, Ministry of Security and Justice, Research and Documentation Centre, The Hague, The Netherlands

Abstract

A brief review of major conceptual notions and empirical findings within the literature on grandparent–grandchild relationships is presented. Four major topics for understanding the intergenerational relationship are addressed: the historical context, the importance of the relationship, changes over individual time, and culture and variation. The focus is on grandparents and grandchildren from Western societies and who are biologically connected.

Historical Context

In the popular and academic literature it is frequently presumed that grandparent–grandchild relationships have become more important in Western societies than ever before. This idea is often motivated by greater availability of grandparents due to increased length of life and decreased fertility (e.g., Bengtson, 2001). Due to these demographic changes, the lives of grandparents and grandchildren overlap for a longer period of time and there are fewer grandchildren per grandparent than in previous times (Uhlenberg, 2009). The demographic changes allow for a more intense relationship between grandparents and grandchildren for a longer period of time (Bengtson, 2001).

Greater freedom among contemporary grandparents strengthened the idea of gained importance. The period of time in which older adults are in good health and unfettered by child care responsibilities and work obligations increased, due to better health care and the introduction of pensions funds in many countries during the 1970s and the 1980s (Laslett, 1991). Although current developments of pension reform aim to reduce opportunities for early retirement and to raise mandatory retirement age to deal with the economic pressures coming along with an aging population, the amount of free time for most people in old age in current Western societies is greater than ever before. New concepts were coined to capture and describe this distinct life phase for older adults, such as the 'third age' (Laslett, 1991). Although increased free time may have induced involvement in social roles that compete with extended family relationships (Silverstein and Long, 1998), having free time is often mentioned as one of the reasons for greater involvement with grandchildren (Herlofson and Hagestad, 2012).

The idea of greater importance of grandparent–grandchild bond is reinforced by several other economic and family transformations in the past decades (Herlofson and Hagestad, 2012). The most important economic transformation is increased employment among women. In earlier cohorts, mothers typically stayed at home to take care of children and household. Contemporary mothers of young children often continue to work at least part-time or return to the labor market after short breaks (Vlasblom and Schippers, 2006). Due to emancipation and a shift in gender roles, female labor participation is greater than before and, alongside with it, the need for child care from beyond the nuclear family increased. As grandparents can be called upon for assistance more than ever before, it is often assumed that their availability in combination with the parent's need for child care increased grandparents' involvement with grandchildren (e.g., Fergusson et al., 2008).

As to family transformations, the increase in divorce among parents is often referred to as the most important transformation affecting the importance of grandparent–grandchild relationships, predominantly because divorce increases the need for child care (Bengtson, 2001). In families of divorce, child care is not easily shared with the former partner, and for that reason, grandparents are more often needed as childminders, in particular when the mother is employed. Hank and Buber (2009) observed across 10 European countries that grandparents are more likely to provide child care when the parent is single than when the parent has a partner. Other family transformations that led to greater need for grandparental involvement is an increase in the number of poor functioning parents, in particular in the United States (Uhlenberg and Cheuk, 2010). In such families, grandparents may take over the parental responsibilities and act as surrogate parents due to drug abuse, illness, incarceration, or poverty in the middle generation. These grandparent-headed households – sometimes referred to as 'skipped-generation' households – modestly increased in the second half of the twentieth century (Uhlenberg and Cheuk, 2010). The restructuring of gender roles and increase in poor functioning parents created the need and opportunity for grandparents to become more involved in one of the most prominent functions of the family as an institute: socialization and nurturance of a child.

Despite the widespread belief of greater importance of the grandparent–grandchild relationship in family life, only few studies exist that examined trends over historical time. Data that allow for examining of changes over historical time, in particular grandparental involvement with grandchildren, are scarce. The few studies that do exist suggest both gained and reduced importance. On the one hand, a study from Finland suggests that older people from an earlier generation generally had more frequent contact with grandchildren than grandparents from more recent cohorts (Lyyra et al., 2010). Likewise, research from Silverstein and Long (1998) indicates that earlier cohorts of grandparents from the United States

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23219-4

had more frequent contact with their adult grandchildren than later cohorts. On the other hand, an increase in grandparental child care provision was observed in the Netherlands (Geurts et al., 2014): grandparental child care substantially increased between 1992 and 2006 and this was linked to increased needs on the part of adult daughters due to higher employment rates and a higher rate of single motherhood. The increase also appeared to reflect greater opportunities of grandparents to provide care as indicated by decreased travel time and less competition among grandchildren because recent grandparents have fewer of them. A similar trend of increased child care provision by other family members – most likely grandparents – was observed in Great Britain (Gray, 2005).

Although empirical support for the assumption of greater importance of grandparent–grandchild relationships in family life is scarce and results are mixed, an abundance of scholarly research show that the sheer availability and freedom of grandparents increased, that the need for grandparental child care increased, and that many of today's grandparents are involved with their grandchildren in terms of child care provision (Uhlenberg, 2009; Fuller-Thomson and Minkler, 2001). These observations provide good reasons to believe that, in many families of Western societies, the grandparent–grandchild relationships are more important than ever before – in particular during the grandchild's childhood.

Importance of the Relationship

The importance of the grandparent–grandchild relationship in contemporary Western societies is mainly given shape through the meaning grandparents attach to their role (Reitzes and Mutran, 2004). Depending on personal opportunities and preferences, grandparents give shape to their role, which reflects their own interpretation of what it means to be a grandparent. Hayslip et al. (2003) argue that the meaning of this role includes a sense of continuity (carrying on the family line, or the sense of living on through the lives of grandchildren), extension of the self (by feeling valued as an elderly person or by vicarious accomplishments through the grandchildren), and satisfaction (by contributing to their grandchild's well-being through help, advice, or indulgence). In addition, grandchildren can be a source of pride and grandparents can derive enjoyment and companionship from the relationship with their grandchildren. The grandparents' freedom in the interpretation of their role is often stressed in the academic literature by referring to what is called 'a roleless' role: a social status without clear cultural expectations and prescriptions. There is only one study that suggests that culture plays a significant role (Herlofson and Hagestad, 2012).

Because of unclear cultural norms about how this role should be enacted, there is a great variety in how grandparents enact their role and therefore also in the importance of the relationship. Earlier research suggested that grandparents can enact their roles by being a 'family watchdog' (Troll, 1983), nurturer, mentor, family historian, and role model (Kornhaber and Woodward, 1981). More recent research examined the content of the relationships between grandparents and grandchildren (contact frequency, activities, intimacy, instrumental help, and authority/discipline) and developed a typology of five grandparenting styles: influential, supportive, passive, authority oriented, and detached (Mueller and Elder, 2003).

The importance of the relationship is mainly manifested through its importance for the middle generation. That is, grandparents can play a significant role in child care provision and, in some cases, even the upbringing of their child. As time beyond working hours is often a luxury commodity, in particular for dual-income parents, grandparental child care provision is presumably of high value to parents, in particular because parents generally find child care provision from their parents more convenient, more beneficial to their child, more trustworthy, and less expensive than care from other child minders (Fergusson et al., 2008). Furthermore, it enables women to be employed outside of the house because it eases reconciliation of child care with work. It is well documented that the intergenerational relationship is important during grandchild's childhood (e.g., Fergusson et al., 2008; Fuller-Thomson and Minkler, 2001; Hank and Buber, 2009). Through their child care activities, grandparents contribute to their family, the society (by increasing employment opportunities for women), and the welfare state (by producing support functions that are absent or would otherwise be produced by the welfare state).

Little attention, however, has been given to the importance of the intergenerational relationship when grandchildren are adults. It is known that the frequency of contact between grandparents and grandchildren declines when grandchildren grow older (Silverstein and Long, 1998). Other studies examining the significance of the intergenerational relationship concluded that the relationship continues to be highly valued, personally meaningful, and potentially important (Kemp, 2005). Adult grandchildren may even contribute to their grandparents' well-being by providing emotional and practical support (Fruhauf et al., 2006). For example, adult grandchildren may introduce new technologies and instruct their grandparents in how to operate them. In this way, grandparents can learn about societal developments through contact with their adult grandchildren. Although such support can also be provided by other young people, for instance, in the context of intergenerational programs, adult grandchildren are more easily approached because many older people maintain contact with younger generations only within the family context. Furthermore, grandchildren, and in particular adult grandchildren, may assist a grandparent in need of care (e.g., Fruhauf et al., 2006), even though they are generally not the first in order of preferred care providers.

To understand the importance of the relationship across generations in Western societies, researchers commonly draw on the intergenerational solidarity framework developed by Bengtson and Roberts (1991). This model distinguishes between structural, consensual, functional, associational, affectual, and normative solidarity. Structural solidarity refers to factors that facilitate or hinder the opportunity for contact between generations. Consensual solidarity indicates the amount of agreement in beliefs and values. Functional solidarity refers to the amount of help and assistance within the intergenerational relationship. Associational solidarity concerns the frequency of contact and shared activities between

the generations. Affectual solidarity involves the amount of emotional closeness as perceived by both generations. Normative solidarity refers to obligations felt regarding the other party in the relationship and expectations regarding the content of the relationship.

Although the intergenerational solidarity model was originally developed to understand parent–adult child relationships (Bengtson and Roberts, 1991), it is applied to grandparent–grandchild relationships as well (e.g., Bengtson, 2001; Silverstein and Marenco, 2001). In particular research focusing on grandparent–adult grandchild relationships uses the model to understand the intergenerational relationship (e.g., Mills, 1999). The model is, however, less suited to understand connectedness during the grandchild's childhood. Because the focus is on dyadic relationships, it is unclear how intergenerational relationships should be understood when it is mediated by a third party. For instance, when grandparents provide child care, should this be understood in terms of solidarity between grandparent–adult child relationships, grandparent–grandchild relationships, or both?

The concern of applying the intergenerational solidarity model to grandparent–grandchild relationships underscores the importance of keeping in mind that the generation in between plays a key role in connecting grandparents and grandchildren. That is, they often serve as a lineage bridge between grandparents and grandchildren by either facilitating or hindering the contact. Likewise, parents shape the opportunity structure for intergenerational contact, for instance, through their choices regarding residential location, parental divorce and the quality of the parent–grandparent relationship (Uhlenberg and Hammill, 1998). Over individual time, however, the role of the middle generation as mediators between grandparents and grandchildren presumably declines in importance. Adult grandchildren can maintain contact with their grandparents independently from their parents and may reestablish the relationship on the basis of their own and their grandparents' terms (Kemp, 2005).

Changes over Individual Time

The grandparent–grandchild relationship is considered to be the most intense before the grandchildren have reached adolescence (Cherlin and Furstenberg, 1986). Although the relationship may continue to be personally meaningful and significant for grandchildren and grandparents in and after adolescence (Kemp, 2005), the relationship presumably becomes less intense when grandchildren grow older for two reasons. First, the initiative for maintaining contact is likely to shift from parents and grandparents to grandchildren. During childhood and early adolescence, parents are most important, as they initiate and facilitate contact with grandparents (Brown, 2003). When grandchildren enter adulthood, the parental influence on the grandparent–grandchild relationship is assumed to become less important and grandchildren may reestablish the relationship on their own terms. Although the grandparents' need for family contact may increase, as these contacts are considered to be more emotionally rewarding at an older age (Carstensen, 1992), grandparents also believe they should not interfere in the lives of younger generations and may be reluctant to contact their grandchildren (Kemp, 2005).

Second, grandchildren's priorities and opportunities for maintaining contact with grandparents decrease. Grandchildren in early adulthood are likely to prefer peer relationships over intergenerational relationships because they place more emphasis on the potential for information gain and future contact (Carstensen, 1992). Moreover, grandchildren face more time restrictions as they take up adult roles such as starting their own families or pursuing careers (Mills, 1999). Kemp (2005) observed that adult grandchildren frequently use their busy lives as a legitimate excuse for not contacting their grandparents, supporting the assumption that limited time restricts grandchildren to contact their grandparents. The reduced importance of parents and grandparents, combined with grandchildren's weaker preferences and fewer opportunities for intergenerational contact, is assumed to weaken the grandparent–grandchild relationship when grandchildren enter adulthood. Cherlin and Furstenberg (1986) even go so far as to say that it evolves into a relationship with limited meaning and little content. Most studies have focused on young grandchildren and showed a decline in contact frequency during adolescence (e.g., Silverstein and Marenco, 2001). The few studies that track grandchildren beyond adolescence also suggest a decline (e.g., Geurts et al., 2009; Mills, 1999; Silverstein and Long, 1998).

The development of the relationship into one of low intensity may at least partly be counteracted by an intense relationship during childhood. The relationship in childhood is of importance because discrepancies in developmental stages are likely to hinder continuation of the relationship when both parties age. Older generations strive to maintain continuity in the intergenerational relationship, while younger generations tend to exaggerate differences to facilitate separation from the family of origin (Harwood, 2001). A strong bond between the parties at an early stage of the relationship may hold back a decline in relationship intensity, even though discrepancies in the developmental stages become increasingly pronounced. Results from three studies support the idea that a strong bond established during childhood positively affects the bond in adulthood. Taylor et al. (2005) observed more positive perceptions and greater satisfaction in the intergenerational relationship if adult grandchildren had coresided with their grandparents during childhood. Brown's (2003) study observed that the quality of adult grandchild–grandparent relationships was higher when grandparents had intensively cared for their grandchildren during childhood. The presumed link between childhood intensity on later relationship outcomes was also supported by a study by Geurts et al. (2014), who observed that more overnight visits, contacts, and child care increased the likelihood that grandparents identify adult grandchildren as a personal and important contact.

Variation between Countries

Grandparent–grandchild relationships take shape within a social-cultural context. Economical and political regimes shape the social conditions that are assumed to play a major

role in variation in intergenerational relationships; it influences the allocation of care responsibilities among state, market, and family (Igel and Szydlik, 2011). Although nonparental child care is often dictated by the reconciliation of mothers' care responsibility with paid employment, families with children at risk can mobilize nonparental support as well. In such families, grandparents may take over some or even all of the parental responsibilities. In the following, variation in grandparental child care provision is briefly described by looking at Europe, China, South Korea, Russia, and the United States.

Across European countries, 58% of grandmothers and 49% of grandfathers took care of a grandchild aged 15 years or younger in 2004 (Hank and Buber, 2009). In European countries with extensive public child care arrangements, grandparental child care is often complementary to these public services. That is, grandparents are occasionally called upon for child care assistance but are generally not needed for daily child care. In European countries with limited public child care arrangements, however, grandparental child care provision is predominantly a substitute for absent services. In particular for full-time employed mothers, grandparents generally provide daily rather than occasional child care (Hank and Buber, 2009).

In China, 56% of grandparents provide child care (Ko and Hank, 2014). Labor migration plays a significant role: about 20% of Chinese elders in rural areas with high migration rates provide full care of their grandchildren (Silverstein et al., 2006). In South Korea, grandparental child care is less common (6% of grandparents; Ko and Hank, 2014). Because child care is widely considered as a primary task for the family, Korean mothers prefer to rely on relatives rather than on public or privately paid services (Ko and Hank, 2014). Russian grandparents – in particular grandmothers – play a significant role in the upbringing of children: One-third of the young adults born in the 1990s grew up with a grandparent in the household (Semenova and Thompson, 2004). Grandparents' significance increased due to increased numbers of full-time employed single mothers, increased poverty, and decreased state provision of child care (Lokshin et al., 2000).

In the United States, 24% of grandparents engage in caregiving activities between 10 and 29 h per week (Fuller-Thomson and Minkler, 2001). About half of the children with employed mothers who received grandparental child care received this child care combined with another arrangement (Uhlenberg and Cheuk, 2010). Because public-financed child care is limited, this grandparental child care is presumably complementary to private services. Next to grandparental child care services in relation to mothers' employment, a substantial number of grandparents also provide non-work-related care. See Hayslip and Kaminski (2005) for an overview on custodial grandparenting in the United States.

Finally, the authors stress that while the coverage in this article is restricted mainly to advanced Western societies, intergenerational relationships of the sort that is discussed are at the very core of extended family life in most of the rest of the world as well. Grandparents parenting their grandchildren are by no means restricted to low-income households in Western urban societies.

Graphical Markov Models: Overview

Nanny Wermuth, Chalmers University of Technology, Gothenburg, Sweden and Medical Psychology and Medical Sociology, Gutenberg-University, Mainz, Germany

Abstract

We describe how graphical Markov models emerged in the past 40 years, based on three essential concepts that had been developed independently more than a century ago. Sequences of joint or single regressions and their regression graphs are singled out as being the subclass that is best suited for analyzing longitudinal data and for tracing developmental pathways, both in observational and in intervention studies. Interpretations are illustrated using two sets of data. Furthermore, some of the more recent, important results for sequences of regressions are summarized.

Some General and Historical Remarks on the Types of Model

Graphical models aim to describe in concise form the possibly complex interrelations between a set of variables so that key properties can be read directly off a graph. The central idea is that each variable is represented by a node in a graph. Any pair of nodes may become coupled, that is joined by an edge. Coupled nodes are also said to be adjacent. For many types of graph, a missing edge represents some form of conditional independence between the pair of variables and an edge present can be interpreted as a corresponding conditional dependence. Because the conditioning set may be empty, or may contain some or all of the other variables, a variety of types of graph have been developed and are used to represent different types of structure.

A particularly important distinction is between directed and undirected edges. In the former, an arrow indicates the direction of dependence of a response on an explanatory variable; the latter is also called a regressor. If, on the other hand, two variables are to be interpreted on an equal standing then the edge between them is typically undirected. For instance, systolic and diastolic blood pressure values are treated as being on equal standing because they are two aspects of a single phenomenon, namely a blood pressure wave.

Graphical Markov models started to be developed after 1970 as special subclasses of log–linear models for contingency tables and of joint Gaussian distributions, where conditional independence constraints are imposed such that conditioning is on all the other variables; see Darroch et al. (1980), Wermuth (1976, 1980). These models are typically represented by undirected graphs with edges that are full lines, called nowadays concentration graphs. The same type of graph were used by the physicist Gibbs (1902) to describe for two systems of particles having the same node sets, one as more complex whenever its nodes have more edges, that is larger numbers of 'nearest neighbors.'

The first extension was to situations in which the variables can be arranged recursively, that is in an ordered sequence, so that each variable turns into a single response to variables in its past and may be explanatory only to other variables in its future; see Wermuth (1980), Wermuth and Lauritzen (1983). This led for single responses to what are now called directed acyclic graphs and for sequences of joint or single responses to the so-called regression graphs, and furthermore to distributions said to be generated over graphs.

For such generated Gaussian distributions, these models include as a subclass the path analyses of the geneticist Wright (1923, 1934). Wright had studied, for his data, sequences of exclusively linear regressions as possible stepwise generating processes. In his graphs, each missing arrow corresponds to the vanishing of the partial correlation coefficient given all remaining variables in the past of a given response, which in Gaussian distributions is a conditional independence constraint. For other types of generated distributions, an important issue is to identify parametric consequences of conditional independences; as for instance for the so-called CG-regressions, see Lauritzen and Wermuth (1989) and Edwards and Lauritzen (2001).

In general, the vanishing of a correlation coefficient may coexist with a nonlinear dependence. Conversely, a substantial partial correlation can occur in spite of conditional independence; for an example, see Wermuth and Cox (1998). Currently, one knows also for jointly symmetric binary variables, generated over a directed acyclic graph, that an arrow vanishes in the graph if and only if there is a corresponding zero partial correlation; see Wermuth et al. (2009). Zero partial correlations given all other variables may reflect conditional independences more generally, provided the distribution is generated over even more specialized types of graph; see Loh and Wainwright (2013), Wermuth et al. (2014), and Wermuth and Marchetti (2014).

The next extensions were to variables of any type so that a missing edge corresponds to a conditional independence. This exploits a proposal by the probabilist Markov (1912): many types of seemingly complex joint distribution may be much simplified by conditional independences. Important issues are defining sets of independences for a graph and criteria to derive all implied independences so that an independence structure captured by the graph becomes well understood; see the section 'Questions Regarding Applications And Statistical Research.'

Further developments include different types of chain graph models; see Cox and Wermuth (1993) and Drton (2009).

The name 'chain graph' reflects a full ordering of the variables into a sequence of joint or single responses and possibly a set of remaining variables that is to capture the context of a study or properties of individuals given at the baseline and hence regarded as given. For parameterizations of Gaussian distributions with different types of chain graph see Wermuth et al. (2006).

Statistical monographs documenting the early development of what are now called graphical Markov models are by Whittaker (1990), Edwards (1995), Lauritzen (1996), and Cox and Wermuth (1996). For surveys of probabilistic aspects, see Pearl (1988) and Studený (2005). For graphical models used in expert systems, see Cowell et al. (1999) and for machine learning, see Wainwright and Jordan (2008).

Special theoretical results, not touched upon here, have been derived under the assumption that a given probability distribution satisfies all independence constraints represented by a graph and no more. Such distributions have been said to be 'faithful to the graph'; see Spirtes et al. (1993).

The existence of a family of faithful distributions means that one can choose a member at random, constrained just by the independences specified by a graph, and this distribution captures precisely the independence structure of the graph. But such an existence result is of no relevance when other constraints are known for subsets of parameters. For instance, the whole family of Gaussian distributions is faithful to concentration graphs, but there is a simple subfamily with additional parameter constraints that is always 'unfaithful' to concentration graphs, see Wermuth (2012: Section 2.5).

More importantly, for data analyses, in which it is crucial to respect known important dependencies, such an existence is also of no relevance. In most research settings, much is known about subsets of parameters because the direction and strength of some dependences derive from substantive theory or from results in previous empirical studies.

Sequences of Regressions and Data Generating Processes

Directed acyclic graphs are a common subclass of all currently known types of chain graph. Distributions generated over a directed acyclic graph result in a stepwise fashion in terms of univariate conditional distributions, also called recursive single-response regressions. These may be compatible with causal interpretations and, therefore, appear attractive, at first sight, for substantive research that is driven by causal hypotheses.

It is however well understood, from randomized clinical trials in particular, that real interventions often result in modifying more than a single response and possibly other features. For instance, a medication that is to reduce blood pressure, will typically affect both systolic and diastolic pressure values. Hence, models that are to be compatible with causal interpretations should contain response variables that may respond at the same time to a change in relevant explanatory variables. This is possible with joint response regressions.

Nevertheless, much of the current literature on causal modeling is based on directed acyclic graphs and on only virtual interventions; see Pearl (2009). With such a virtual intervention, those changes in single response are recorded that result by fixing the values of some variables. This may for instance be treatments. One removes arrows pointing to these variables in a given graph and estimates treatment effects given these additional independence constraints. Implicit is the assumption that a given joint family of distribution remains unchanged, otherwise.

These recorded changes in virtual interventions, even though they are often called 'causal effects,' may tell next to nothing about actual effects in real interventions with, for instance, completely randomized allocation of patients to treatments. In such studies, independences result by design and they lead to missing arrows in well-fitting graphs; see, for example, **Figure 9** below in the last section.

Sequences of regressions in joint and single responses are the most attractive chain graph models for observational as well as intervention studies. For these models, residual associations among the responses may often be regarded as secondary features. But, standard univariate estimation methods for regression coefficients may lead to distorted estimates whenever two associated joint responses on equal standing have disjoint subsets of regressors, a situation that has become known as seemingly unrelated regressions. When strong residual dependences remain after one has been regressing each response component separately on two different sets of regressors, then distorted parameter estimates may result, see Haavelmo (1943), Zellner (1962), and Drton and Richardson (2004).

For known types of chain graph other than regression graphs, recursive generating processes may not exist since response components are conditioned on other joint responses on equal standing. While substantive theory may occasionally support such models, this type of conditioning is typically counterintuitive whenever one main aim of an analysis is to identify consequences of interventions or early predictors for joint responses. But now, graphical criteria are available to decide whether the regression graph of a given sequence of joint or single regressions defines the same independence structure as another chain graph, that is whether they are Markov equivalent; see Wermuth and Sadeghi (2012: Section 7), and here the section 'Markov Equivalence of Regression Graphs.'

For applications, arguably the most important developments concern conditions under which the regression graph can be used to trace development, to predict implied dependences in addition to implied independences, as well as graphical criteria for possible confounding effects when some variables are ignored or subpopulations are studied.

Regression Graphs as Partial Summaries of Data Analyses

We give here two examples of data for which corresponding detailed statistical analyses have been published; see the Appendix in Wermuth and Sadeghi (2012) for the first and the Appendix in Wermuth and Cox (2013) for the second set of data.

In the regression graphs derived for both examples, the dashed lines capture remaining associations among two joint responses and full lines, for the context variables, reflect that conditioning is on all the context variables simultaneously. Estimation is for both data sets by local modeling of each response alone on its past and of response pairs on the union

of their directly explanatory variables. When there are only independence constraints concerning responses and no seemingly unrelated regressions, local maximum-likelihood (m.l.) estimates lead directly to proper m.l. estimates for the joint distribution; see Cox (2006) for such types of general principles.

In both the following examples, data analyses lead to traceable regressions; see Wermuth (2012). This means that for a given ordered sequence of single and joint responses, the resulting regression graph permits one not only to read off independences, but also more importantly for most applications, sequences of directed edges show pathways of development.

Tracing of paths is always possible for joint Gaussian distributions whenever each edge in its regression graph represents a substantial conditional dependence; see the section Questions Regarding Applications And Statistical Research. This may not be possible with graphs of some structural equation models; see Wermuth (1992). More importantly, sufficient conditions for traceability using just the graph, are now known for other types of distributions generated over regression graphs.

Data on Chronic Pain Treatment

For some medical data, Figure 1 shows a first ordering of the variables. This ordering was derived in discussions by physicians and statisticians, prior to the analyses.

We are grateful to Judith Kappesser, now Department of Psychology, Liebig University of Giessen, for letting us use her data. They are for 201 chronic pain patients who have been given a 3-weeks stationary treatment at a chronic pain clinic. Two main research questions are: which development is most influential for success or failure of treatment and is it necessary to include information on the patient's site of main pain?

The response of primary interest is self-reported success of treatment, measured 3 months after discharge by a score summarizing several aspects of the illness. Among the context variables, capturing features that cannot be modified, were age, gender, lower or higher level of formal schooling, and the number of other previous illnesses. Only those are shown in Figure 1 that had sizeable dependences to the responses of main interest.

Figure 1 Initial ordering of variables in the chronic pain study for a sequence of regressions. Variables within a same box are treated on an equal standing. Variables in any one box are considered conditionally given all variables their past, listed within boxes to their right.

There are a number of intermediate variables. Before and after a 3-week stationary treatment, questionnaire scores are available of depression and of intensity of pain ranging from 'no pain' to 'pain as strong as imaginable.' The chronification score incorporates different aspects, such as time since onset of pain, spreading of pain, use of pain relievers, and the patient's pain treatment history. Main site of pain here has two categories: 'back pain' and pain on the 'head, face, or neck.'

The regression graph of Figure 2 summarizes some aspects of the statistical analyses. Throughout, symbol $\perp\!\!\!\perp$ means independence, symbol $\not\perp$ means dependence and symbol | is to be read as 'given.' The graph shows, in particular, which of the variables are needed so that for any given response, adding one more of the potentially explanatory variables does not improve prediction. Site of pain is an important intermediate variable since it is a node along a direction-preserving path of arrows pointing from level of schooling to treatment success, hence should be part of any future study of chronic pain.

Some of the directions and type of dependences, which cannot be read off the graph, are as follows. Patients with many years of formal schooling (13 years or more) are more likely to be head-pain patients, the others are more likely to be back-pain patients, possibly because more of them have jobs involving heavy physical work. Back-pain patients have higher scores of pain chronicity, reach higher stages of intensity of pain before treatment and report higher intensity of pain after treatment.

Never captured by the graph alone are nonlinear dependences, here of Y on Z_a. Treatment success, Y, is low whenever higher levels of intensity of pain remain after treatment, Z_a. But at relatively lower levels of Z_a, treatment is clearly the more successful when the intensity of pain at discharge is lower, Z_a. The model fits the data well since for each response taken separately, no indication was found that adding variables, further

Figure 2 Well-fitting sequences of regressions which have a statistically significant relation for each edge present in the graph. Discrete variables are drawn as dots, continuous ones as circles. For instance, the two context variables are marginally independent, written as $B \perp\!\!\!\perp V$ and response Z_b is conditionally independent of V given A, B, U; $Z_b \perp\!\!\!\perp V \mid A, B, U$, also A is marginally dependent on B, written as $A \not\perp B$, while U depends on V given A; $U \not\perp V \mid A$. *Note*: Full arrows in regression graphs are sometimes also drawn as dashed-line arrows and dashed lines as so-called arcs, which are full lines with arrow-heads at both ends.

nonlinear or interactive effects would improve prediction and no strong dependences remained among the residuals of the joint responses on equal standing.

One important path of development is that patients with shorter formal schooling are more likely to get chronic back-pain and patients with chronic back-pain get help too late and respond less well to the type of treatment offered in the chronic pain clinic. This suggests as possible interventions to modify the type of treatment for the back-pain patients or, much more ambitiously, to raise the general level of formal schooling.

Data on Child Development

Here we use data of 347 families participating in the 'Mannheim study of children at risk.' We are grateful to Manfred Laucht, Central Institute of Mental Health Mannheim, for permitting a reanalysis of the data.

The study started with a random sample of more than 100 newborns from the general population of children born near Mannheim, Germany. This sample was completed to give roughly equal subsamples, in each of nine level combinations of the two types of adversity at birth, categorized to be at levels 'no, moderate, or high'; see Laucht et al. (1997). In other words, there was heavy oversampling of children at risk for motoric or cognitive deficits in later years and a random sample that serves as a control group, which provides, in particular, comparable norm values.

The recruitment of families stopped with 362 children. All measurements were reported in standardized form using the mean and standard deviation of the starting random sample. Of the 362 German-speaking families who entered the study when their first, single child was born without malformations or any other severe handicap, 347 families still participated when their child reached the age of 8 years.

There are joint responses of main and of secondary interest at age eight and at age four-and-a- half years. Each of these contains two components of possible deficits: cognitive or motoric; see the derived graph in Figure 3.

One main difference to previous analyses is that we averaged three different assessments of each of two types of risk: recorded at birth, at 3 months, and at 2 years. In both cases, this can be justified by the six observed pairwise correlations being all nearly equal; see for example, Wermuth (2013). These averaged scores are risks at 2 years for motoric deficits, labeled X_r, and for cognitive deficits, labeled Y_r. Two possible additional risks were identified at 3 months after birth, a score called unprotective environment E, and a binary variable H, which records whether the child had to be hospitalized during the first 3 months after birth.

The graph shows in particular for motoric deficits of the child at the age of 8 years, X_8, that no arrows are pointing to it from risks at 3 months, E, H, or from any variable for the cognitive side, Y_8, Y_4, Y_r, given information on the more recent motoric deficit, X_4 and the risk for motoric deficits, X_r. By contrast, cognitive deficits at the age of 8 years, Y_8 depend directly on unprotective environment at 3 months, on being hospitalized up to 3 months, as well as on motoric deficits at 2 years, given both more recent deficits, Y_4, X_4. A tentative interpretation is given later using Figure 7 in the next to last section.

The coding of variables implies that all dependences are positive so that deficits accumulate with each additional regressor. Some of the effects are accelerated compared to merely linear dependences. This is not reflected in the graph alone in Figure 4, but in Wilkinson's notation which adds to the graph sums of highest-order effects, as shown in Figure 3.

Questions Regarding Applications and Statistical Research

Here, we first list questions that arise in general when new statistical models are applied, and then give partial answers and references for sequences of regressions:

1. Are studies available in which the new models have been used fruitfully?
2. Can well-fitting models be derived from data and be tested as hypotheses formulated for future data?
3. What additional possibilities do the models offer to gain better insight into given research questions, especially to an understanding of development over time?

Figure 3 A well-fitting regression graph in the child development study; arrows point from regressors in the past to responses in the future; dashed lines are for dependent responses given their past; full lines are for dependent early risk factors given the remaining context variables.

$$
\begin{array}{ll}
Y_8 : Y_4 + X_4^2 + E + H & X_8 : X_4^2 + X_r \\
Y_4 : Y_r + X_r^2 & X_4 : Y_r + X_r^2 \\
Y_r : E^2 & X_r : E + H
\end{array}
$$

Note: In this notation supplementing the graph, every square term implies that also a main effect is included in a regression; see discussions of Wilkinson's notation in McCullagh and Nelder (1989).

As to (1), case studies with sequences of regressions, which include joint responses, continue to accumulate. In addition to the two examples summarized here in the previous section; see for instance Cox and Wermuth (1996), Cheung and Andersen (2003), Hardt et al. (2004), Smith (2009), Hardt et al. (2011), Marchetti et al. (2011), Schier et al. (in press), and Solis-Trapala et al. (in press).

As to (2), one most attractive feature of sequences of regressions is that their fitting requires typically no new estimation techniques. Standard methods are often available; for linear regressions, see Weisberg (2014), for categorical responses, see Cox (1972), McCullagh and Nelder (1989), Andersen and Skovgaard (2010). To screen for nonlinear or interactive effects, see Cox and Wermuth (1994). Regression graphs represent hypotheses about generating processes which can be tested in future studies.

When seemingly unrelated regressions are hypothesized, direct estimation methods are based for discrete variables on generalized linear models; see Marchetti and Lupparelli (2011), for joint Gaussian distributions, estimation is possible with structural equation models; see, for example, Bollen (1989). But as mentioned before, when strong residual dependences remain in Gaussian seemingly unrelated regressions, especially for small sample sizes, estimates may be far from the population values.

One may also regard seemingly unrelated regressions as so-called reduced models and embed them in larger so-called covering models for which estimation is again standard; see Cox and Wermuth (1990). Often m.l. estimates in the covering model are not far from those obtained by separate regressions and are then good approximations to the m.l. estimates in the reduced model.

As to (3), a number of new results have been obtained in the last years. We concentrate on the following few, discussed in the next three sections:

1. graphical conditions for the Markov equivalence of two regression graphs, to be used for possible alternative interpretations or for different types of fitting algorithm;
2. conditions and criteria for deriving implied independences and implied dependences from a given regression graph;
3. ways of distinguishing different types of confounding that are implied by a generating process when some variables are unobserved, that is marginalized over, or a population subgroup is studied; that is, when there is conditioning on the levels of some variables present in the generating process.

Markov Equivalence of Regression Graphs

Two different graphs are Markov equivalent if they define the same independence structure. The independence structure of a regression graph, with a given set of nodes and an ordering for the responses, is determined by its list of missing edges for node pairs i,k. Such a graph has possibly two types of undirected edges; full lines between context nodes and dashed lines between responses on equal standing, as well as arrows starting at a regressor and pointing to a response; see **Figure 1** to recall the meaning of these terms.

A missing full i,k-line between two context nodes means conditional independence given all remaining context nodes, and a missing dashed i,k-line between two response nodes on equal standing means conditional independence given other nodes in the past of i and k. If a possible i,k-arrow pointing from k to i is missing, this means conditional independence given all other nodes in the past of i except for k.

A V-configuration in such a graph, often called just a V, consists of three nodes with two uncoupled nodes, called the outer nodes, i,k. Both outer nodes are coupled to an inner node. There are two types of Vs in regression graphs, named collision and transmitting Vs. In each of the three possible types of collision Vs:

$$i\text{---}\circ\prec k, \qquad i\succ\circ\prec k, \qquad i\text{---}\circ\text{---}k\,,$$

the two edges are removed when the inner node is marginalized over. In each of the remaining transmitting Vs, both edges are removed by conditioning on the inner node.

Directed acyclic graphs consist exclusively of arrows so that there can be only the middle V above, where two uncoupled regressors point to a common response. Graphs of only full lines, often called concentration graphs, have only transmitting Vs, while graphs of only dashed lines, often called covariance graphs, have only collision Vs.

These three types of graph are subclasses of regression graphs. The names of the last two derive from parameters in joint Gaussian distributions. For such a distribution, zero off-diagonal elements, σ_{ik}, in the covariance matrix capture a marginal independence, and zero off-diagonal elements, σ^{ik}, in the concentration matrix, the inverse of the covariance matrix, capture a conditional independence given all the remaining nodes.

Two different types of regression graphs, which have the same node set and the same set of missing edges but different types of edge for some node pairs, are Markov equivalent if and only if their sets of collision Vs coincide, even though for any given V, there may be any of the three types of collision Vs above; for a proof, see Wermuth and Sadeghi (2012). One example is shown in **Figure 4**.

The graph on the left of **Figure 4**, resulted from a retrospective study, with more variables than reported here. Questions about their childhood were answered by 283 adult females when visiting a general practitioner for some minor health problems; see Hardt et al. (2008). No nonlinear or interactive effects were detected.

The well-fitting graph contains two binary variables, level of formal schooling and severe sexual abuse during childhood, as well as three quantitative measurements. Age in years is recorded directly, the other variables being derived from questionnaires. Family status indicates the recalled social standing of the family during early childhood. Family distress includes psychological disturbances and alcohol or drug problems of the parents.

Figure 4 A regression graph that is Markov equivalent to a concentration graph.

From the Markov equivalence to the concentration graph on the right of **Figure 4**, one knows, for instance, directly that sexual abuse is independent of the level of formal schooling given knowledge about the family status. This implication may be derived from the defining independences of the graph on the left or be based on the following separation result in graph theory. If in an undirected graph with three disjoint subsets α, β, c of the given set of nodes, every path between α and β has a node in c, then α is separated from β by c, that is removal of set c leaves α and β disconnected. For concentration graphs, this separation implies $\alpha \perp\!\!\!\perp \beta | c$; see, for example, Lauritzen et al. (1990).

Figure 5 shows instead a regression graph on the left that is Markov equivalent to the covariance graph on the right. It is the simplest case of the seemingly unrelated regressions with regressors labeled 3 and 4 and responses labeled 1 and 2. For instance, it follows from the graph definitions that edge $1 - - - 2$ means $1 \not\perp\!\!\!\perp 2 | 3, 4$ on the left and $1 \not\perp\!\!\!\perp 2$ on the right.

As discussed in the next section, to transfer such equivalence results for graphs to a distribution generated over a regression graph, this distribution has to mimic some properties of joint Gaussian distributions; see also Wermuth and Sadeghi (2012).

Implied Independences in Directed Acyclic Graphs

Work on reading all implied independences off a directed acyclic graph started with a path-breaking, complex theorem, called d-separation; see Pearl (1988) and Geiger et al. (1990). For the reduction of d-separation to the above described separation criterion for undirected graphs; see Lauritzen et al. (1990).

A third criterion is based on matrix representations of graphs, named their edge matrices. Square edge matrices contain zeros for missing edges, ones for edges present, and ones along the diagonal to extend the graph theoretic notion of adjacency matrices in such a way that some sums or products of edge matrices describe transformations of graphs; see Wermuth et al. (2006). It gives the most direct criterion in that it leads to a matrix with the dimensions of two disjoint node subsets α and β: if this is a matrix of zeros only, then it is established that the graph implies a desired conditional independence.

In particular, let four disjoint subsets α, β, c, m partition the node set of a directed acyclic graph, let further $a = \alpha \cup m$, and $b = \beta \cup c$, then the transformation to the edge matrix $\mathcal{P}_{a|b}$ parallels the transformation of parameters in linear sequences of single-response regressions to the matrix $\Pi_{a|b}$ of least-squares regression coefficients with Y_a as response and Y_b as regressor. For joint Gaussian distributions, the submatrix of $\Pi_{a|b}$ for rows α and columns β is zero, $\Pi_{\alpha|\beta.c} = 0$, if and only if $\alpha \perp\!\!\!\perp \beta | c$. In general, $\mathcal{P}_{\alpha|\beta.c}$, the corresponding submatrix of $\mathcal{P}_{a|b}$ is zero if the given graph implies $\alpha \perp\!\!\!\perp \beta | c$.

Figure 5 A regression graph that is Markov equivalent to a covariance graph.

For directed acyclic graphs, the three types of criteria have been proven to be equivalent; see Marchetti and Wermuth (2009). For combining independences in sequences of regressions, the generated distribution has to satisfy additional conditions that mimic some properties of Gaussian distributions.

Independence properties of joint Gaussian distributions have been nicely summarized in the information theory literature, together with other properties that hold for all probability distributions; see Lněnička and Matúš (2007: Definition 1). To combine pairwise conditional independences in general sequences regression just as in the Gaussian case, two properties are needed; see Sadeghi and Lauritzen (2014). We call the presence of the intersection property the 'downward combination' and the presence of the composition property the 'upward combination' of pairwise independences.

A graphical illustration of these two properties is given for just three nodes i, h, k in **Figure 6**. In this simplest case, upward and downward combination mean, respectively,

$$(i \perp\!\!\!\perp h \text{ and } i \perp\!\!\!\perp k) \Rightarrow (i \perp\!\!\!\perp h, k) \Rightarrow (i \perp\!\!\!\perp h | k \text{ and } i \perp\!\!\!\perp k | h)$$

$$(i \perp\!\!\!\perp h | k \text{ and } i \perp\!\!\!\perp k | h) \Rightarrow (i \perp\!\!\!\perp h, k) \Rightarrow (i \perp\!\!\!\perp h \text{ and } i \perp\!\!\!\perp k)$$

Essential for both properties in the above two equations is the first implication. The second implication holds in all probability distributions and just serves to motivate the chosen names. For instance, upward combination means above to move from two simple to two more complex conditional independence statements; expressed more generally: it means moving to increased conditioning sets.

On the left of **Figure 6** is a complete regression graph with joint response $\{h, k\}$, on the right a complete directed acyclic graph with single responses ordered as. (i, h, k)

A sufficient condition for the intersection property is to have a strictly positive distribution; see San Martin, Mouchard & Rolin (2005) for extensions. Sufficient for the composition property is that to every nonlinear effect there is also a linear one and that to every interactive effect there are also main effects. Such linear or main effects have to be substantial to be relevant for a model fit; see Németh and Rudas (2013) for an example when this property does not hold in a sociological context. In such instances, models more complex than graphical models are needed such as those included for discrete variables in the class of marginal models; see Bergsma and Rudas (2002).

Deciding on Implied Dependences

Edge matrix results for directed acyclic graphs have been extended to the more general types of regression graph and, more importantly, to inferring that a generating regression

Figure 6 Two regression graphs where removal of the *hi*-edge and the *ki*-edge leads to $i \perp\!\!\!\perp h, k$, provided independences combine upward (left) and downward (right).

graph implies the conditional dependence $\alpha \not\perp\!\!\!\perp \beta | c$ if $\mathcal{P}_{\alpha|\beta.c} \neq 0$; see Wermuth (2012).

To permit conclusions about dependences implied by sequences of regressions, the generated distribution has to have, in addition to upward and downward combination of independences, nonvanishing parameters to each edge present in the graph and it has to be dependence-inducing, a property also called singleton transitivity. Distributions with all above mentioned properties have been called traceable, since their regression graph can be used to study pathways of development.

In any specific application, there may be special parametric constellations that lead to path cancellations and hence to preventing us from recognizing dependences that are implied by the given generating process for other parametric constellations. This cannot happen, when all variables are coded, as in the Mannheim study, to have higher values for stronger adversities, for higher risks and for increased deficits and only linear dependences are observed or dependences that are accelerated compared to the linear effects. In addition, prediction of the strength or direction of induced associations may vary with the measures of dependence used; see Jiang et al. (in press).

For linear dependences among three variables, there are already three types of possible parameters: covariances, concentrations, and regression coefficients. A detailed notation is needed to understand their relations:

$$\sigma_{12|3} = \sigma_{12} - \sigma_{13}\sigma_{23}/\sigma_{33} \qquad [1]$$

$$\sigma^{23.1} = \sigma^{23} - \sigma^{12}\sigma^{13} \qquad [2]$$

$$\beta_{1|3} = \beta_{1|3.2} + \beta_{1|2.3}\beta_{2|3} \qquad [3]$$

These three nice recursive properties were derived by different authors. Here, $\sigma_{12|3}$ denotes the conditional covariance of 1,2 given 3; see Anderson (1958), $\sigma^{23.1}$ the concentration of 2,3 marginalized over 1; see Dempster (1969), and $\beta_{1|3.2}$ the population coefficient of 2 when regressing 1 on both 2 and 3; see Cochran (1938) for the property.

The right-hand sides of the above equations contain, for trivariate Gaussian distributions, the parameters representing dependence in different graphs for three nodes. These parameters are in eqn [1] for a covariance graph, in eqn [2] for a concentration graph and in eqn [3] for a directed acyclic graph: with 1 as response to 2, 3 and 2 as a response to 3; see **Figure 8**.

The coefficient of 3 when regressing 1 only on 3, denoted by $\beta_{1|3}$ can be regarded as the result of two paths: of $\beta_{1|3.2}$, an arrow pointing from 3 to 1, and of a sequence of two arrows starting at 3 and pointing to 1 via 2 with effect $\beta_{1|2.3}\beta_{2|3}$. Sometimes, the first is called the direct effect of 3 on 1, the second the indirect effect, and $\beta_{1|3}$ the overall effect.

If for instance $0 = \sigma_{12} = \sigma_{13}$ in eqn [1], then $\sigma_{12|3} = 0$ and consequently also $\beta_{1|3.2} = 0$ in eqn [3] so that 1 has no dependence on 2 and 3 jointly. This is the Gaussian case of the more general notion of combining independences upward since here $(1 \perp\!\!\!\perp 2 \text{ and } 1 \perp\!\!\!\perp 3) \Rightarrow 1 \perp\!\!\!\perp 2,3$.

With more variables, eqns [1]–[3] generalize by adding everywhere a larger conditioning set in eqns [1] and [3], to get, for instance, $\sigma_{12|c}$, $\sigma_{12|3c}$ and $\beta_{1|3.c}$, $\beta_{1|3.2c}$, and by adding a larger marginalizing set in eqn [2] to get $\sigma^{23.m}$, $\sigma^{23.1m}$. The three measures of dependence relate for a node set consisting of 1, 2, 3, c, m as.

$$\beta_{1|3.c} = \sigma_{13|c}/\sigma_{33|c} = -\sigma^{13.m}/\sigma^{11.m}$$

derived via the sweep operator by Dempster (1969), and explaining why $0 = \sigma_{12|3} = \beta_{1|2.3}$ and $0 = \sigma^{23.1} = \beta_{2|3}$ above when all variances such as $\sigma_{33|c}$ and all precisions, such as $\sigma^{11.m}$, are nonzero in the two single-response regressions.

For joint Gaussian distributions, the dependence-inducing property can be proven in its simplest form using eqn [1]: for $1 \not\perp\!\!\!\perp 3$ and $2 \not\perp\!\!\!\perp 3$, one may have at most $\sigma_{12|3} = 0$ or $\sigma_{1|2} = 0$ but never both. In the case of $\sigma_{12|3} = 0$, the induced correlation, $\rho_{12} = \sigma_{12}/\sqrt{\sigma_{11}\sigma_{22}}$, has also been named a 'spurious correlation,' since the dependence between the two variables 1 and 2 can be 'explained away' by conditioning on their common neighbor 3. For three variables, the dependence-inducing property can be written as:

$$(1 \not\perp\!\!\!\perp 3 \text{ and } 2 \not\perp\!\!\!\perp 3) \Rightarrow \text{at most } 1 \perp\!\!\!\perp 2|3 \text{ or } 1 \perp\!\!\!\perp 2 \text{ but never both}$$

It has been proven that binary variables are dependence-inducing; see Simpson (1951). But there are constellations of counts for which both independences $1 \perp\!\!\!\perp 2|3$ and $1 \perp\!\!\!\perp 2$ seem to hold and a decision would have to be based on outside information.

Independence-Predicting and Independence-Preserving Graphs

The results for deciding on implied independences and dependences, based on an induced edge matrix, have been extended to derive regression graphs implied by a given generating process when, for instance, the order of the responses or the conditioning sets, or the marginalizing sets are changed; see Wermuth and Cox (2004).

Then the so-called independence-predicting graphs, may be derived by using the partial closure operator (Wermuth et al., 2006) as well as sums and products of edge matrices, but each of these operations has also an intuitive translation into closing special types of paths in graphs; see Wermuth (2012).

For instance, when in a study, different from the Mannheim one, the same variables were available except for cognitive deficits after 4 years, Y_8,Y_4, one predicts, from the starting graph in **Figure 3** and an unchanged order of the remaining variables, the regression graph in **Figure 7**. In this case, it is just a subgraph of **Figure 3** obtained by removing nodes

Figure 7 The regression graph induced by Figure 3 after marginalizing over Y_8 and Y_4.

and edges of Y_8 and Y_4, no additional dependences are induced.

By contrast, when X_8 and X_4 are not available, all remaining variables turn out to be directly explanatory for Y_8. One consequence of this finding is that it is more important for psychologists and psychiatrists to evaluate also motor development than it is for physicians to take also cognitive development into account.

Typically, one cannot use such an induced regression graph to condition on or marginalize over more nodes and still see what the starting graph would have implied for this case, while this is possible with the so-called independence-preserving graphs. Starting from directed acyclic graphs, three types of such graphs have been proposed, the MC-graphs by Koster (2002), the maximal ancestral graphs by Richardson and Spirtes (2002), and the summary graphs by Wermuth (2011). For their relations and proofs of Markov equivalence, see Sadeghi (2013). To construct these types of graph within the program environment R, see Sadeghi and Marchetti (2012).

Summary graphs may be derived for the more general regression graphs and, if obtained after marginalizing only, they provide graphical criteria to detect confounding.

Graphical Representations of Distortions

For traceable regressions, the regression graph represents an independence structure and a partly specified dependence structure. The graph can be viewed as a hypothesis of how sequences of single or joint responses generate a joint distribution when, for instance, corresponding point estimates of parameters are taken as the population values. For reliable interpretations of estimated effects, it is important to prevent, if at all possible, any important, sizable distortion of the actual population parameters.

Different types of distortions of a treatment effect may be avoided by using regression graphs and appropriate study designs. To see this, we show in **Figure 8** simple cases of under-conditioning, of over-conditioning, and of direct confounding by using a node crossed by two lines, $\not\emptyset$, to indicate that the variable is to be marginalized over and a node surrounded by a square, $\boxed{\bigcirc}$, to indicate that the variable is to be conditioned on.

For instance, by using label 3 for treatment and label 1 for the outcome or response to 2 and 3, the graph on the left of **Figure 8** shows one important intermediate variable, labeled 2, which could be, say, compliance of the patients to treatment.

Figure 8 Left: Under-conditioning for $1 \perp\!\!\!\perp 3|2$ by ignoring an intermediate variable. Middle: Over-conditioning for $2 \perp\!\!\!\perp 3$ by selecting levels of the common response 1. Right: Direct confounding for $1 \perp\!\!\!\perp 2|3$ by ignoring the common explanatory variable 3 for 1 and 2; generating a double edge $1 \circ\!\!\!

Figure 9 Left: full randomization for T_p leads to removal of $T_p \leftarrow U$, randomized allocation of individuals to selected levels of a more recent treatment, T_r, given results of the intermediate outcome A, leads to removal of $T_r \leftarrow U$ and of $T_r \leftarrow T_p$ and to the presence of $T_r \leftarrow A$; right: the summary graph obtained by marginalizing over U; path $Y \dashrightarrow A \prec\!\!\longleftarrow T_p$ explaining the indirect confounding of $Y \leftarrow T_p$ when response Y is regressed on only T_p and T_r.

Abstract

Graphics are a powerful tool for representing and analyzing data. Interactive graphics are ideal for exploratory data analyses, for checking data quality, for investigating assumptions, and for uncovering information. Standard statistical displays (e.g., histograms and scatterplots) are empowered by the addition of interactive features such as direct querying, reformatting, and linking. Displays of complex multivariate data become workable in an interactive implementation. Mosaic plots for categorical data and parallel coordinate plots for continuous data are two recent examples.

Introduction

Everyone is accustomed to seeing graphical displays used for presentation purposes: in scientific articles, newspapers, and magazines. Yet graphical displays may be used for exploratory purposes too, for investigating data sets and for uncovering the information hidden in them. Exploratory graphics are different. The aim is not to present information, but to use the graphics to uncover information. Static printed graphics can be useful for exploratory work, but the real gain lies in using interactive graphics on a computer.

In all the following examples it is assumed that exploratory analyses are being carried out, that each graphic is part of a broader analysis and that they are drawn to aid the analyst, not to present the information to others. This is why there are few scales given. The analyst will know the approximate scaling and can always query the graphic on screen to get exact values, not only along axes, but for any point or object. In general, a single presentation graphic is drawn to convey information to a potentially large and varied audience, whereas a large and varied collection of exploratory graphics are drawn to extract information for a single person, the analyst.

Graphics are useful for checking basic assumptions and for getting a feel for data. Figure 1 shows a bar chart of gender from an insurance data set. Unusually there are 7 codes for gender, three made sense (firms are neither male nor female) and the rest were errors.

The histogram for policyholders' birthdates for the same data set was also revealing (Figure 2). The tall white column to the left represents missing values for the variable (mainly firms again). There is a small isolated column at 1900 (missings originally coded as '00'?) and there are some very recent dates of birth, surely errors for car-driver insurance data. This is a large data set (over 50 000 cases) and some errors may be expected, but it is extraordinary how often data sets that have been purportedly quality checked still have errors in them. Incidentally, the dip in the histogram is due to low birthrates during the war.

Figure 1 Bar chart of gender of car insurance policyholders.

Assuming major errors have been corrected or removed, graphics are valuable both for checking old ideas and for generating new ones. After the historic 1990 Irish Presidential election it was hypothesized that Mary Robinson had won because she got the women's vote. Data from the last MRBI survey before the election suggests otherwise. Figure 3 shows a bar chart for the preferences for the three candidates linked to a spine plot for gender (in a spine plot all column heights are the same and column widths represent the counts, so highlighted proportions are directly comparable). The proportion of women intending to vote for Mary Robinson was only slightly higher than the proportion of men. Linking to another spine plot shows that urban voters were more important for Mary Robinson's win.

Background

Presentation graphics (*see* Graphical Methods: Presentation) have been used for a long time. Exploratory graphics are newer, not because people did not appreciate their value, but because without a computer it was not efficient to draw many variations of many different displays. John Tukey led the way with his innovative and provocative book, *Exploratory Data Analysis* (Tukey, 1977) (*see* Exploratory Data Analysis: Univariate Methods) although, curiously enough, the book was written slightly too early, before personal computers were becoming commonplace. Thus he emphasizes pencil and paper methods like stem and leaf plots for continuous data. These are like histograms laid on their side with each bin having a width of a power of 10. The advantages are the simple construction by hand and the listing of each value individually. The disadvantages are the dependence on a very limited range of bin sizes and the unsuitability of the method for anything other than small data sets. Imagine a stem and leaf plot for the car insurance data set of Figure 2.

More recent computer-oriented books for EDA include Cook and Swayne (2007) and Theus and Urbanek (2007).

Figure 2 Histogram of years of birth of car insurance policyholders (from 1900 to 1995).

Figure 3 Bar chart of candidates' support linked to spine plots for gender and location. Results from the last MRBI survey before the 1990 Irish Presidential Election. Thanks to Jack Jones and the Market Research Bureau of Ireland for permission to use the data.

There has also been much related work outside statistics for which Spence (2007) and Ward et al. (2010) are good sources. In none of these works is a substantial formalization of exploratory graphics attempted. Considering that presentation graphics have been around much longer and yet Wilkinson's groundbreaking work (Wilkinson, 2005) first appeared in 1999, this is not surprising. Furthermore, exploratory analyses are by their nature interactive and dynamic and so the process is difficult to explain on the printed page. Some of the best sources of information and examples can be found on the web using the keywords of this article and/or author names as search parameters.

Interacting with Displays

Interactive Features

Graphics may mislead. For instance, bar charts will look similar whether they are based on 50 or on 5000 cases. (The survey in Figures 3 and 4 was based on 1000 interviews.) It is important to be able to check any impressions gained.

Figure 4 Direct querying of a bar. How many women supported Mary Robinson?

Sometimes this might mean carrying out the corresponding statistical test (e.g., a chi-square test for comparing bar chart proportions), but a first step is to directly query the graphic, as in Figure 4.

Direct querying is useful in all displays, especially when it is context sensitive. The same action may be used for each part of each plot and yet provide different information according to which part of which plot is queried. Other steps that may be carried out to gain more insight are to rescale the graphic (e.g., change the bin size in a histogram), to reformat the display (e.g., switch the axes of a scatterplot), to reorder the display (e.g., order the categories in a bar chart by count), to zoom in (e.g., concentrate on an outlying cluster of points in a scatterplot), or to select various groups of points and link them to their representation in other displays (Unwin, 2012).

Histogram bin sizes, which are small, pick out gaps and identify preferred values, while large bin sizes emphasize overall trends. Figure 5 shows two histograms of math marks for 126 Irish schoolchildren. Notice how one version picks out the typical gap below the pass mark of 40 and the other does not.

Scatterplots can be extremely informative tools for revealing the relationship between two variables, but the scales, the aspect ratio of the axes, the size and color of the points can all affect how they look. For large data sets with extensive overplotting (i.e., many points are drawn at the same location on the plot), some form of density estimation (*see* Probability Density Estimation) is necessary or there is a risk the data set may be misunderstood. Figure 6 shows a scatterplot of the birth weights of 4000 babies plotted against the estimated duration of pregnancy. A coarse density estimation has been used whereby black dots represent single cases and the brightest white ones at least 30 cases. It is clear where the majority of the data is concentrated.

Figure 5 Histograms of math marks out of 100 for a group of Irish schoolchildren.

Figure 6 Babies' birth weights plotted against duration of pregnancy.

Neither drawing sunflowers at each point with the numbers of petals representing the numbers of points, nor jittering the data (adding small random components to each point to reduce the overlapping) are serious solutions for large data sets like this (although both suggestions are to be found in the literature). Sounder solutions have been suggested by several authors including Carr et al. (1987) and Hyndman (1996), but would be better implemented interactively. Single displays optimized on a particular criterion cannot reveal all the structure in the data. An interesting problem for interactive scatterplots is how to display both highlighted and unhighlighted distributions informatively.

Variations of scatterplots may be used to display subgroup distributions in parallel, e.g., income of those surveyed by job category. The resulting parallel dot plots are a valuable initial exploration tool for smaller data sets, but parallel box plots are more effective for large data sets as in Figure 7.

Bar charts are good for comparing absolute numbers, but are not good for displaying proportions. Simple pie charts are good for emphazising shares, though it is difficult to compare the sizes of individual sectors and too often they are drawn with irrelevant three-dimensional features and other distracting distortions. Spine plots are best for comparing proportions based on selections, but can only deal with one selection at a time (see Figure 3 above). Switching between bar chart and spine plot representations interactively is one solution.

Figure 7 Box plots of salaries by job category in a bank.

Linking

Linking means that points selected in one display are highlighted in all other displays. Selecting a subgroup may identify an outlier within the group in another plot. There may be patterns within subgroups which mask each other when the data for all groups are shown together. Highlighting area-based plots is straightforward, an area corresponding to the size of the selected group is colored. Highlighting point displays is complicated by overplotting, as mentioned above in relation to scatterplots. The best solution for box plots is to be to draw two box plots, one for all the data in the background and second for the highlighted data on top. This idea is due to Wills (Unwin et al., 2006).

Linking is central to successful interactive graphics in the way it provides insight into multidimensional structure. Not just points in graphics may be linked, but cases, scales, orderings, colors may be linked in any kind of window. In this sense querying is just a form of linking.

Interfaces

All of these tools are exploratory in nature and only work effectively when they are interactive. If you have to wait for the screen to clear and a graph to redraw, you will have forgotten why you wanted the change in the first place. Interactivity implies an intuitive interface, flexible commands, and a fast response. Command-line interfaces are valuable for the precise control they offer and the ease with which they can be recorded. For exploratory work it is direct manipulation of the objects on screen which is important and it is rarely of interest to know how a conclusion was first discovered, as it is common to find much better ways of showing results after you have first discovered them. All components of a graphic display (bars, axes, points, legend, etc.) may ideally be queried, moved, rescaled, and reformatted. To avoid clutter on screen, it is helpful to use cues to hint at what is possible rather than to fill the screen with visible controls. To protect the user from possible unwanted side effects of their actions, warnings and undos are beneficial.

Dynamic Graphics

The term 'dynamic graphics' refers to graphical displays that move, such as rotating plots, grand tour displays, or animations controlled by sliders. (A slider is a control that allows the user to change the value of a parameter of a model in real time and see the affected displays update continuously. *See* Data Desk or Tierney, 1990.) While the resulting dynamic displays may be informative, it is the interactive control in the hands of the user, which is most useful, and in this sense they are a specialist subset of interactive exploratory graphics.

Multivariate Displays

Continuous Variables

Modern graphical tools are very good for exploring many variables at once. Scatterplot matrices (a matrix display of scatterplots of all possible pairs of variables) have often been suggested for continuous variables, though they are inefficient in their use of space. For up to about eight variables (the number depending on the screen's resolution and the analyst's eyesight) they can be used for exploratory purposes with linking.

Parallel coordinate displays, e.g., **Figure 8**, are primarily for large numbers of continuous variables. Each variable is represented by a vertical axis and individual cases are joined by lines. There is an attractive geometric duality, pointed out by Inselberg (2009), that a point in a scatterplot is represented by a line in a parallel coordinate display and vice versa. Interactive tools are essential for these plots for two reasons: the order of the axes affects what can be seen, so it has to be possible to change the order easily; the large numbers of lines for a data set of even moderate size makes it essential to be able to temporarily hide points and lines. Categorical variables can also be displayed on their own axes (Kosara et al., 2006). Since there is no natural order of categories for most such variables, being able to reorder categories interactively is also valuable. While there is, in principle, no limit to the number of axes, which may be displayed in a scrollable window, it is clear that these displays provide only limited insight to the full multidimensional structure.

Categorical Variables

Interest in investigating multivariate categorical variables has grown with the rise of data mining. The large data sets which banks, retailers, and other commercial organizations want to study often include many categorical variables. Survey data sets commonly do too, but it is rare to find visualizations of such data. Mosaic plots are one way of uncovering the multivariate structures. Although first discussed in general by Hartigan and Kleiner in 1981, it was only in the late 90s with the addition of interactive features that they revealed their true potential (Hofmann, 2000). A mosaic plot in its original form is constructed by dividing up the horizontal and vertical axes in turn by each new variable. **Figure 9** shows a diagram for the Titanic data set (Dawson, 1995). Initially the horizontal axis was divided up according to the numbers in each class, then the individual columns were divided vertically by age, then the resulting cells were each divided horizontally by gender. Finally, the numbers surviving in each group have been highlighted.

This mosaic plot allows the comparison of survival rates by gender within class and age group. The higher survival rates of the female adults compared to the males are obvious. Redrawing with a different order of variables (gender, age, class) permits direct comparisons of survival rates by class within each gender and age group. There are gaps drawn between the cells for two reasons: the display is easier to interpret and empty cells can be shown (for instance, there were no children in the crew of the Titanic).

Alternative versions of mosaic plots include: (1) the same bin size display, where each cell has the same size; this is good for identifying patterns of empty combinations and for comparing highlighted rates for all combinations; (2) fluctuation diagrams, where each cell's size is proportional to the count of the combinations which it represents, but the cell is drawn at a fixed position on the grid. Fluctuation diagrams have the advantage of maintaining a clearer structure, but can

Figure 8 A parallel coordinate plot of the points by event for the mens' decathlon at the Sydney Olympics 2000. The medal winners have been highlighted.

Figure 9 Mosaic plot of the Titanic data in the order class, age, gender with survivors highlighted.

be very inefficient in their use of space in comparison to the original format. The alternating of horizontal and vertical axes is an arbitrary restriction, and Hofmann has introduced double-decker plots, where only the horizontal axis is divided, as a particularly insightful way of looking at association rules.

One of the most useful approaches for analyzing multivariate data, especially with large data sets, is to study subsets of the data in parallel as in **Figure 7**. Trellis displays (Sarkar, 2008) are a more sophisticated version and draw individual displays for each subset in a structured panel display. As in a mosaic plot, the panels are defined by a hierarchical succession of variable splits. Unlike mosaic plots the panels are all the same size. Each panel may display any one of a number of basic statistical graphics, e.g., a box plot or a scatterplot. The art in a successful trellis display lies in the choices of panel plot and of how to split the data set into subgroups. For this reason it would be useful for them to be interactive, but at the time of writing trellis displays are only available in a static form.

Figure 10 A biplot of the 13 variables and 178 cases of the UCI Wine data set.

Multivariate Projective Displays

The multivariate displays mentioned thus far show all the raw data. An alternative is to concentrate on projections of the data onto specially chosen lower dimensional spaces. Good projections reveal almost all the information in the data, albeit in the transformed space. Biplots are so-called because they show both the projected points and also the axes of the variables (for continuous variables) or the category level points (for categorical variables) in the projection space (Gower and Hand, 1996). **Figure 10** shows the UCI wine data set with the second group highlighted. This projection separates the groups fairly well. Long axes show that the corresponding variables are well represented in the projection space. Biplots have many attractive properties, but remain two-dimensional representations. The larger the number of variables, the less likely it is that a biplot can reveal the major features of a data set, but the addition of interactive tools enhances the capabilities of biplots substantially (Hofmann, 1998).

The first major innovation in exploratory graphics was none of these tools, it was the rotating plot (Fisherkeller et al., 1974 in Cleveland and McGill, 1988), in which a succession of two-dimensional images gives the impression of rotation in three dimensions. This is a natural extension of a scatterplot, is excellent for three-dimensional continuous data, and is fun to use, but for higher dimensional data sets it is not so practical. In that case it can be used in a different way, displaying three-dimensional projections of the data. Many methods of identifying 'interesting' projections have been discussed and the most effective implementation seems to be a directed grand tour. The grand tour was designed to rotate through all possible three-dimensional projections of a data set of continuous variables and the analyst would decide which of the resulting projections gave him insight into the data. Directed grand tours make use of projection pursuit indices to guide the user toward revealing projections (Cook and Swayne, 2007).

Specialist Displays

Missing Values

In the histogram in **Figure 2** there was a special column for recording the numbers of cases with no values for that variable. Missing values are a problem for large data sets and any initial overview of the data needs to check for numbers of missings and for any structure among them. Some statistical methods cannot handle cases with missings. A simple approach is the missing value plot as in **Figure 11**. There is a bar for each variable. The solid part of the bar on the left represents the cases with values, and the blank section on the right represents the missing values. Bars can be queried and selected to give a rough

Figure 11 A missing value plot for variables from a patient survival study. A subgroup missing on only two variables is highlighted.

idea of associations. In the figure it is clear that many cases are missing on a large number of variables.

This kind of display cannot reveal more complex structure. Displays of the multivariate patterns of missing values are one promising approach, though interactive versions are not yet available.

Weighted Displays

In data sets arising from surveys or based on geographic areas it can often be the case that individual data points are of differing importance: the unemployment rate in London should have a greater weight than the unemployment rate in Stratford-upon-Avon. Some authors have suggested using bubbles instead of points in dot plots and scatterplots, where the size of the bubble is proportional to the weighting variable. This can be effective for small numbers of cases, but generally leads to overplotting problems. Area-based displays such as histograms, bar charts, or mosaic plots have no such problems and counts are simply replaced by sums of weights. This can lead to very striking and informative differences in displays. The left-hand histogram in Figure 12 just about shows a single county with the highest percentage of blacks among the over 400 counties in the five US Midwest States. Most counties have low percentages of blacks. The right-hand histogram has the same horizontal scaling, but the height of the bins is now proportional not to the number of counties, but to the aggregate black population in the bins. Most blacks live in counties with relatively higher percentages of blacks. It is, of course, necessary that the weighting variable is additive! Population is fine, population density is not (see Unwin et al., 2006).

Statistical Tools and Plots

Surprisingly, and disappointingly, statistical graphics rarely make use of statistical tools. There are a few exceptions. Some packages offer the option of displaying box plots with confidence intervals around the medians. Some packages offer the chance of plotting error bars round means. SAS have software

Figure 12 Histograms of black population percentage by US Midwest county, unweighted (left) and weighted by black population (right).

(JMP) where circles are drawn round subgroup means to enable graphical detection of whether differences are significant or not. However, the last example illustrates one of the problems. JMP offers several different options because there is no agreed optimal way of comparing several means simultaneously. The same problem would arise with bar charts and more seriously with mosaic plots – there are so many possible statistical tests, that it is not easy to specify a universally acceptable default. The solution will be to offer the various options interactively.

The Future

Advances in statistical graphics have not been due to improvements in screen resolution. The best exploratory graphics are simple displays. What makes them powerful is the speed and flexibility with which they can be manipulated and combined. It is the increase in computing power which has been crucial for modern interactive graphics. More powerful computing has also led to the development of computer-intensive analytic procedures and these have sometimes been combined successfully with graphics. Evaluation of projection pursuit indices and rotating plots is one example. Smoothing methods such as loess and spline models are another.

A major requirement for all statistical methods is whether they can be scaled up to deal with huge data sets. Area-based graphical tools such as histograms and bar charts can in principle be used for data sets of any size, but interaction is necessary to catch details and explore links between variables. Much more needs to be done to cope with displays for large numbers of variables, and interactive capabilities will be essential.

Statistical graphics has grown in fits and starts. There are many attractive ideas, some general principles, but little theory. Real progress will only come with a successful formalization, so that the future can build on the successes of the past. This is something to look forward to in all senses of the phrase.

Software

The displays in this article have been taken from screenshots. There has been no attempt to pretty them up, they illustrate exploratory analyses in progress. Most are from MANET (Unwin et al., 2006) and could be drawn in Mondrian (www.rosuda.org/Mondrian/), a couple are from Data Desk (www.datadesk.com). Other software also offers interactive capabilities, but the degree of interactivity varies considerably. For up to date information on software, check statistical Web sites.

Abstract

This article surveys briefly the history of presentation graphics, principles of usage, and applications. Many popular charts were invented by social scientists centuries ago, although social scientists in the twentieth century were more reluctant to use them than were natural scientists and business people. Recent developments in graphics theory and may change this pattern. Well-designed graphics summarize both models and data. They conserve space and highlight essential features with modern computer software that implements recent technical advances in graphics, graphical displays may prove to be one of the most powerful research tools available to social scientists.

Figure 1 shows a graphic of death rates against birth rates per 100 000 population for 27 selected countries in a 1990 UN databank (Wilkinson, 1999b). The contours in Figure 1 show two concentrations of countries. One, to the left, has relatively lower death rates and small-to-moderate birth rates. The second, toward the upper right, has high death rates and extraordinarily high birth rates. The curve in the middle of the contours shows that the overall relation between death and birth rates is curvilinear.

The single plot in Figure 1 contains three graphs: (a) a point graph (collection of points) whose labels show country names; (b) a set of contours based on a kernel density estimate (Silverman, 1986) that represents the concentration of the countries; and (c) a LOESS smoother (Cleveland and Devlin, 1988). The graphic also includes three guides for our understanding. The first is a general geometric object called a form that is, in this instance, a line delineating zero population growth. Countries to the left of this line tend to lose population, and countries to the right tend to gain. The other two are guides that demarcate axes for the represented space. Other examples of guides are legends and titles.

Each of the constituent graphical elements in Figure 1 has a long lineage in the history of statistical charts. Scatterplots of points and contours are several centuries old, and regression smoothers are at least a century old. The use of a rectangular coordinate system to locate graphs within a frame demarcated by axes predates by centuries Decartes' eponymous Cartesian coordinate system. We shall review briefly the history of statistical graphics and charts.

The lines, colors, typography, proportions, and other aspects of Figure 1 have been chosen to facilitate communication of the ideas and models underlying the chart. We do not need to resort to platitudes such as, 'A picture is worth a thousand words' to understand that this graphic comprises a relatively substantial analysis of the data. We shall review briefly the topic of graphics principles which can help us devise effective ways to display analyzed data.

The world of charts is enormous. Principles can guide us through that world, but there are many alternatives for representing one or more variables in a graphic. In the final section, we shall present some of these choices and use them to derive additional guidelines for developing effective presentations.

Figure 1 Plot of 1990 death rates against birth rates for selected countries.

History

The contours, or level curves, in **Figure 1** represent a map. This representation is based on a statistical function that maps birth rate and death rate onto a density. Any value on this density can be derived from a corresponding pair of birth rate and death rate values taken from the domain of values within the frame bounded by the two displayed scales. The geometric space in which this mapping is embedded is three-dimensional. The first two dimensions are birth rate and death rate, and the third dimension is density.

The technical mathematical terms in the previous paragraph (contours, level curves, map, function, onto, density, value, domain, frame, bounded, scales, geometric space, and dimensions) are derived from ordinary language, often ancient, describing the physical world. This correspondence between the world of charts and the physical world is not coincidental. Charts are maps of abstract worlds. The word chart and the word cartography have the same root (Latin *charta*, a piece of paper or papyrus). The Greek word for geometry means 'land measurement.' A scale (in Latin) is a ladder. We map in order to organize our world in our mind. However, our world is larger than the domain of geography. As Pinker (1997) has argued, abstract reasoning is built on metaphors for reality. We manipulate abstractions by making them analogous to concrete objects.

Statistical charts are maps, but it does not suffice to simply describe them as abstract geography. The history of statistical charts contains remarkable leaps from a world of continuous rectangular (or spherical) space to other worlds that are categorical (worlds with gaps), multidimensional (worlds beyond three dimensions), and topological (worlds in abstract coordinate systems). Funkhouser (1937), Tilling (1975), Beniger and Robyn (1978), Fienberg (1979), Robinson (1982), Stigler (1983), Tufte (1983, 1990, 1997), Collins (1993), Wainer (1997), and Wainer and Velleman (2001) document these leaps. These references also contain numerous examples of graphics, ancient and modern, that represent significant landmarks in this history. The remainder of this section will highlight a few.

Physical coordinates were used by Egyptian surveyors as early as the third millennium BCE for locating points on land (Beniger and Robyn, 1978). By the beginning of the second millennium CE coordinates were used to locate nongeographic entities. Funkhouser (1936) shows an example of a line graphic of planetary movements on a space–time grid produced by an unknown astronomer in the tenth or eleventh century. Not surprisingly, one of the 'planets' is the Sun.

Cartesian coordinates were devised by Descartes for locating points in abstract space, particularly for representing equations underlying his analytic geometry (Funkhouser, 1937). However, relatively few seventeenth or eighteenth century embeddings of observed data points in Cartesian coordinates have been found. (Funkhouser, 1937; Tilling, 1975). Scientists of the Enlightenment sometimes regarded graphics as dilettantish, and if they used them at all, it was for geometrical diagrams or maps of algebraic functions rather than for plots of raw data (Beniger and Robyn, 1978). Social scientists of this period focused on collecting tables of state statistics that could be perused in detail without resorting to graphical approximation (Beniger and Robyn, 1978, although see Stigler, 1983). Beniger and Robyn (1978) and Wainer and Velleman (2001) discuss notable exceptions to these observations (graphics by Wren, Halley, Huygens, Plot, Lister, Priestley) but conclude that the important varieties of what we now call the statistical chart did not arise until the work of Playfair in the late eighteenth century.

Playfair graphed the data of the state, the root of the word statistics. He invented the pie chart, the circle chart, the categorical bar chart, the area chart, and he adapted other geometric forms in novel ways to graph data over time and space. Wainer and Spence (1997) provide a brief biography of Playfair's fascinating life and the charts he created.

Other widely used graphical forms were developed in the nineteenth and early twentieth centuries. Beniger and Robyn (1978) and Stigler (1983) summarize a number of these. Density bars were used by Guerry in 1833 to display crime by age groupings. Pearson adopted this form for representing a frequency distribution and named it a histogram. Minard developed a number of schematic maps overlaying statistical data on geography. Florence Nightingale introduced polar area charts. The age–sex pyramid (a dual histogram) was introduced by F. A. Walker, Superintendent of the US Census in 1874. The sample cumulative distribution plot was introduced by Galton in 1875.

If charts are maps of abstract worlds, we might conclude that guiding principles for graphics usage could be derived from the psychology of perception and cognition in the physical world. Indeed, recent psychological research has tended to support the simple statement that the more graphics adhere to the rules of the physical world, the more likely we are to extract and process the information in them, reliably and accurately. Section Choices covers this area.

Principles

Over the centuries of their history, various charts have emphasized communication (e.g., Snow's map of cholera deaths in London, reproduced in Tufte, 1983), persuasion (Fletcher's map of the distribution of ignorance in nineteenth century England and Wales, reproduced in Wainer, 1997), and graphic design (e.g., Playfair's chart of imports and exports of England to and from North America, reproduced in Tufte, 1983). These criteria are, of course, not exclusive. Some charts incorporate all three (e.g., Minard's compound chart of Napoleon's troop losses in the Russian campaign, reproduced in Tufte (1983).

Not surprisingly, modern critics of charts have tended to align themselves along these same dimensions. Communicators (e.g., Cleveland, Kosslyn) have conducted experiments to determine rules that improve the transfer of information from chart-maker to chart-viewer. Persuaders (e.g., Holmes, 1991) have evaluated charts on the basis of their psychological impact. Designers (e.g., Herdeg, 1981) have applied aesthetic criteria. Others (e.g., Tufte, 1983) have adopted the criteria of the communicator, and the methods of the designer. None of these approaches can claim exclusive validity. Since scientists are more interested in rules that foster accurate communication

of replicable results, however, this section will focus on communication.

Evaluating graphical communication has been the province of psychology, in the subdisciplines of human factors, ergonomics, and applied cognitive science. For almost a century, human factor psychologists have developed methods and criteria for evaluating graphics. Military psychologists, for example, have conducted randomized experiments to test the effectiveness of aircraft cockpit displays.

Psychologists gave much less attention to the perception of statistical graphics until a statistician, William Cleveland, published a series of experiments designed to identity aspects of charts that helped or hindered accurate decoding of quantitative data (Cleveland and McGill, 1984). (Beniger and Robyn, 1978, cite a number of statisticians' informal studies of the effectiveness of popular charts in the 1920s, but these did not induce many psychologists to study the topic more formally.)

Cleveland used paper-and-pencil tests containing simple graphical elements – points, lines, angles, areas, colors – generated randomly by a computer. His subjects gave magnitude estimates of the values generating the instances of each element. From these estimates, he derived and analyzed error rates. **Figure 2** summarizes the main result of these experiments. The top of the figure (BEST) represents elements that resulted in fewer errors and the bottom (WORST) represents those with more.

Cleveland's hierarchy gives us a start in designing effective displays. All other things being equal, we might choose to use a bar chart instead of a pie chart because judgments of position on a common scale and judgments of length are both more accurate than judgments of angle. There are exceptions to these rules, however (see the following discussion of **Figure 3(b)**). A chart is more than the sum of its parts; elements interact in the context of a chart to suppress or enhance errors. Kosslyn (1994) summarizes relevant psychological studies in the extensive notes at the end of his book.

Figure 2 Cleveland (1994) graphical features hierarchy.

Others have provided numerous general rules for effective graphical communication. The following guidelines are derived from Bertin (1981), Tufte (1983), Cleveland (1994), and Kosslyn (1994).

Avoid clutter. Especially, do not clutter the data region inside the plotting frame demarcated by axes. Tufte constructs a data/ink ratio and urges us to maximize it by removing irrelevant detail. This exhortation has value as long as we do not remove redundant features that can reinforce an accurate perception. Most writers agree that one should avoid jazzy textures (especially stripes), gratuitous colors, excessive tick marks and grid lines, ornate fonts, and unnecessary embellishment. Avoid visual illusions due to pseudo-3D and other gratuitous use of color, angles, area, or volume in a 2D plotting world.

Seek simple geometric forms – straight lines, circles, triangles, squares. When it helps to simplify a relationship, use transformations (logs, square roots) to convert curves to straight lines, for example. Use polar coordinates when variables are cyclical (astronomical perceptual, directional).

Sort and organize. This is especially important for complex graphics. Usually, one should sort the values of a dependent variable (the range of the graph), but other sorts can help viewers navigate and perceive structure. Bertin (1981) has numerous examples showing the value of simple and multivariate data sorts. **Figure 12** shows an example.

Annotate extensively. Make legends comprehensive and informative. Figure captions should describe the source of the data and explain the relation of the data to the graphic. Note exceptions (see **Figure 6**).

Choices

Rules guide, but examples instruct. We need to consider specific choices for specific problems to understand exceptions to rules. The graphic representation problem is often expressed as one of choosing the proper chart type for a given set of data. This is an unhelpful way to express the problem, however. As Wilkinson (1999c) shows, different chart types with their own popular names are often mirror images or simple transformations of each other. Instead, we will examine several basic problems confronting the designer of a scientific graphic: geometry (choosing the type of graphical element for a chart), coordinates (choosing a coordinate system for the chart), and uncertainty (representing random error).

Geometry

The following examples were selected to illustrate principles, not exhaust possibilities. It is organized by the configuration and number of variables, categorical and continuous, that we wish to graph.

One variable

Figure 3 shows five different ways of representing values on one categorical variable. The data are from 1606 respondents to the 1993 General Social Survey (Davis et al., 1993). Respondents were asked, 'How many sex partners have you had in the last 12 months?' Those reporting more than four partners

Figure 3 Reported number of sexual partners (General Social Survey, 1993).

(some reported up to 100) were consolidated into the last category. There were 1466 responses in the resulting six categories.

The upper left graphic is a bar chart of the frequencies of occurrence of each category. Bars are most suited for displaying either magnitudes referenced against zero (anchored bars, as in this figure) or a range of values on a continuous scale (range bars, as in Figure 7).

Anchoring bars at zero can sacrifice resolution when no data values exist near zero; this creates substantial white space in the plotting area (Cleveland, 1994). In these cases, dots are preferable to bars because we do not need to include zero on the scale. The upper right graphic shows a dot plot of the same variable. In this case, we would prefer the bar version because there are several values near zero and it is easier to anchor the bars visually on the partner categories. The locations of both the dots and the tops of the bars are easily decoded on the vertical scale.

The third graphic in Figure 3 is a pie chart of the proportions of total category frequencies. The general antipathy statisticians have toward pie charts is misinformed. Pie charts are not always bad, although the issues on when to use them are complex. In general, bar charts are more suited to absolute judgments and pie charts are more suited to judging proportions (Simkin and Hastie, 1987). Pie sectors near a fourth or half of a pie in size are judged especially accurately. When there are many sectors, however, pies are not usually appropriate. In this example, the bar chart would be more suitable.

The fourth graphic is a divided bar chart, which is nothing more than a pie chart in rectangular coordinates. Divided bars do worse than pies in studies of graphical perception

(e.g., Simkin and Hastie, 1987). Cleveland (1994) provides several examples to show why they are generally a bad choice.

The fifth graphic is a 3D pie chart. This is probably the worst of the popular ways to represent proportions. Three-dimensional graphics are not in themselves harmful. What creates the problem with the 3D pie chart is the distortion of angles that the perspective projection produces. In the 3D pie, the single partner category seems to cover almost 75%; the actual coverage is 68%.

Some users and computer programs apply line or area elements (see Figure 7) to categorical variables. Popular examples are line graphics of means in analysis of variance, or area graphics of profiles across categories. These elements should generally be avoided with categorical data. Spacings between categories (even ordered categories) are not fixed, so slopes of line segments or profiles between categories are meaningless.

Figure 4 shows five ways of representing one continuous variable. The data are per-capita consumption of spirits for each of the 50 US states (Bureau of the Census, 1986). The top graphic is a classic histogram overlaid with a kernel density estimate (Silverman, 1986). Histogram bars look like ordinary bars, but they measure areas rather than intervals and they rest on a continuous scale rather than on a set of categories. Histograms are more useful than kernels when we are interested in displaying frequencies within intervals, especially when the intervals themselves are bounded by meaningful, round units. Kernels are more useful than histograms when we are looking for a smooth estimate of a continuous distribution.

The next graphic down is a dot histogram (Chambers et al., 1983; Wilkinson, 1999a). This display represents each observation with a dot located at its scale value. If several values coincide on the scale, the dots are stacked vertically. This display is most suited for small samples, when every value is to be displayed.

The graphic below that is a stripe plot (Chambers et al., 1983). A vertical stripe occurs at each data value. This display can handle more cases than the dot plot, although it is not suitable for large datasets.

The graphic following is a jittered density (Chambers et al., 1983). Random error is added to each value so that the plotting symbols do not overlap. This display is designed to handle roughly the same conditions as the stripe plot.

The last graphic in Figure 4 is a box plot, or schematic plot (Tukey, 1977). As Tufte (1983) notes, Tukey's plot is based on an earlier display that represents the quartiles of a distribution. In that earlier plot, the whiskers cover the range and the box covers the midrange. Tukey improved on this design by scaling the whiskers to allow for outliers. The display in Figure 4 shows how important this feature can be. Two states (Nevada and New Hampshire) have unusually large values (see Figure 6), possibly due to gambling and cheap liquor, respectively. The box plot is a clean representation of the summary values we usually want to see – the median, the twenty-fifth and seventy-fifth centiles (hinges), the extreme values (usually bounding the range), and possible outliers (outside values).

Figure 4 Consumption of spirits in gallons per capita, by US state, 1986.

Two Variables

Figure 5 shows four ways of representing two categorical variables crossed. The data are from the 1993 General Social

Figure 5 Number of reported sexual partners during previous year by reported level of happiness among 1462 respondents to 1993 General Social Survey. Third variable is proportion of respondents in each sexual partner category.

Survey used in Figure 3. The additional variable is general happiness, as measured by the response to the question, 'Taken all together, how would you say things are these days – would you say that you are very happy, pretty happy, or not too happy?'

The upper left plot shows a 3D bar chart of happiness against number of sexual partners. The vertical scale is the proportion of respondents within each partner category. This graphic has the disadvantage that short bars tend to be hidden by long ones. Generally it should be avoided.

Figure 6 Consumption of spirits in gallons per capita by US state vs number of deaths from chronic liver disease and cirrhosis per 100 000 by US state, 1986.

The graphic to the right is a tiled bar chart. This graphic uses color or gray scale to indicate the relative frequency of each category combination. However, as Cleveland's research has shown, the use of color or gray scale to encode continuous values is problematic (Cleveland, 1994).

The next graphic below shows a paneled categorical plot. Instead of using an extra dimension in 3D, we use an extra categorical dimension in 2D to panel the plot. This is probably the most effective method for handling the extra dimensionality required for representing the frequencies, plus the two categories. The bottom panel shows a multiple divided bar chart. This layout has the same problems as the single divided bar chart (see **Figure 3**). Cleveland (1984) shows an example of this graphic and offers a more effective dot plot alternative.

Figure 6 shows the most popular way of representing two continuous variables crossed with each other – the scatterplot. The data are per capita consumption of spirits for each of the 50 US states, used in **Figure 4** (Bureau of the Census, 1986). The additional variable is number of deaths from chronic liver disease and cirrhosis per 100 000 people, by state. This scatterplot has been enhanced in a number of ways. The bordering

Figure 7 US patents issued from 1880 to 1980.

box plots help us to assess the marginal distributions of the variables and highlight the Nevada and New Hampshire outliers. The smoother shows the conditional mode of deaths (estimated mode of deaths given consumption). This was computed through kernel regression (Scott, 1992). This particular smoother limits itself to areas where there are relatively more data values, so it provides a conservative estimate of trend.

Time series data require special treatment. **Figure 7** shows four examples. The data are number of US patents issued in the century from 1880 to 1980 (Wilkinson et al., 1996). The top panel shows a line element representing the series. Lines are most useful when a series is relatively smooth. The next panel shows a point element with a superimposed LOESS smoother. Points are best when we supplement them with a smoother; they tend to obscure time order if used alone, unless the series is especially smooth. The third panel shows spikes. These are vertical lines best used to reveal deviation from a constant level. This panel displays the residuals from the LOESS smooth. The lowest panel shows an area chart for the raw series. This highlights trend but prevents the use of confidence intervals and other enhancements to the plot. Generally, it should be avoided. Cleveland (1994) discusses other graphical representations for time series data.

Figure 8 shows three ways of representing a categorical variable crossed with a continuous variable. The data are based on 80 graduate students over a 10-year period in a US psychology department (Wilkinson et al., 1996). Graduate Record Examination Advanced Psychology Test scores are plotted against whether or not the students eventually received their PhD.

The first graphic employs a dot for the mean and a range bar to represent a 95% confidence interval on the mean. The bars do not overlap, which suggests that the advanced test can help identify those who achieve a PhD. (Interestingly, neither the Verbal nor the Quantitative test scores predicted graduation in this sample.)

The second graphic is a notched box plot (McGill et al., 1978). This is a variation on the box plot that not only conveys more of the important data landmarks than the classic confidence interval plot but also provides an approximate confidence interval of its own. If the data are independent samples from identically distributed populations that are lumpy in the middle (approximately normal in their midrange), then comparing the notches yields an approximate 95% test of the null hypothesis that the true medians in the population are equal. In this example, the notches do not overlap, reinforcing what we concluded from the confidence intervals on the means. Because it relies on the median instead of the mean, the notched box plot procedure is more robust against outliers.

The third graphic is a dot plot (Wilkinson, 1999a). Used frequently in the medical literature, this plot shows every data point. In a small sample (e.g., clinical case study), a dot plot can be useful for readers who wish to consider every data value. However, it is of little use in making informal graphical inferences concerning group differences. It is best to think of grouped dot plots as unadorned one-dimensional scatterplots within categories.

Figure 8 Advanced Psychology Graduate Record Examination (GRE) scores for 80 students taken from 10 years of a graduate psychology program. Students are grouped by whether or not they were awarded a PhD.

Three variables

Figure 9 shows a triple crossing of categorical variables. The data are from the 1993 General Social Survey used in **Figures 3** and **5**. The additional variable is gender (observed by the interviewer, not reported by the respondent). We ask whether

Figure 9 The number of reported sexual partners during last year by reported level of happiness among 1462 respondents to 1993 General Social Survey. The third variable is the proportion of respondents in each sexual partner category.

the relationship between reported happiness and number of sexual partners differs by gender.

The top plot in the figure shows a paneled graphic. The format is similar to a Trellis display (Becker et al., 1996), but the labeling of the paneling variables (happiness and gender) is placed outside the plotting area to improve readability.

The middle plot collapses happiness into a legend in order to reduce the number of panels. This is a popular method for saving space, particularly when representing factorial layouts in ANOVA and other designs. It has several problems. First, the line segments used to highlight trends have slopes that depend on the particular spacing and arrangement of partner categories. Unless we employ an external scaling procedure to

Figure 10 Birth rate and death rate vs literacy for selected countries.

Figure 11 Difference between death month and birthday by occupational category.

determine the spacing of the partners categories, we have scant justification for using these lines. Second, the collapsing introduces a symbol choice problem. It is difficult to find symbols that are easily distinguishable for more than a few categories. The symbols collide, as well, at the upper end of the horizontal scales.

The lower plot introduces an even less appealing alternative. Clustered bar charts are used widely but they have several defects. First, it is difficult to discern separate patterns for the categories. One needs to focus on one set of bars to do this, but there is visual interference from the other bars in each cluster. Second, these bars can become quite thin with more than a few categories. Decoding this graphic is problematic.

Figure 10 shows a triple crossing of continuous variables. The data are from the UN databank used in Figure 1. The additional variable is literacy (percentage of the population that can read). We ask whether literacy is related to birth and death rates taken together.

The upper plot is a 3D frame that includes a contoured regression surface and a scatterplot. The contours (as opposed to a wire-frame or rendered surface) help viewers discern literacy levels in different elevations of the plot and keep the surface from hiding the data. Coloring the contours improves the coherence of the surface.

The lower plot is a 2D frame that includes the same contoured surface plus a scatterplot of symbols whose size is proportional to literacy. This plot makes it easier to decode specific *xyz* triplets.

Some critics tend to eschew 3D surface plots, but they have their uses. As Wilkinson (1999c) argues, surfaces elicit a holistic impression of a function. They are less useful for decoding individual values, however. Perhaps the best compromise is to present both displays simultaneously to provide different structural views. Another alternative is to categorize one or more of the variables and display the results in a paneled plot such as those in Figure 9.

Coordinates

We do not ordinarily think of charts being embedded in different coordinate systems, except for certain scientific graphics such as polar plots. Some chart types, such as radar charts, pie charts, and horizontal bar charts are nothing more than popular charts in unusual coordinate systems. Wilkinson (1999c) provides numerous examples.

Figure 11 shows two different graphics in different coordinate systems, based on data from Andrews and Herzberg (1985), contributed by C. O'Brien. The data are months since their last birthday during which members of different social groups died. The upper plot shows a paneled horizontal area chart produced by rotating a vertical area chart 90 degrees (exchanging x and y coordinates in this case). This graphic reminds us that horizontal bar charts are a coordinate transformation of a vertical bar chart, not a new chart type.

If it makes sense to consider a death one month before a birthday as being more similar to a death one month after, than to one six months after, then we might want to plot these variables in polar coordinates. The lower plot shows a profile plot of the same results.

Figure 12 contains a triangular coordinate plot. Mosteller and Tukey (1968), Bishop et al. (1975), and Wainer (1997) show examples of this type of plot. The data are from the UN dataset used in Figure 1. The variables represent expenditures in US dollars per person for health, education, and the military.

The outside tick marks signify how to read the scales. Grid lines collinear with ticks demarcate values on the three scales. Iraq and Pakistan, for example, allocated most to military spending and least to education and health. Costa Rica spent more than 40% on education, almost 50% on health, and less than 10% on the military. While triangular coordinates may be used most frequently in analysis of mixture models in

Figure 12 Percentage per-capita spending on education, military, and health.

Figure 13 Sex partners vs feelings about the Bible (GSS survey responses).

industrial experiments, they can also be useful for social science models involving tradeoffs or compensatory mechanisms.

Uncertainty

There are two chief methods for representing error in a graphic. The first is sharp: error bounds are represented by clear edges, points, or lines. The second is fuzzy: error is represented by blurring an estimate.

Figure 13 shows two sharp ways of representing error in a graphic. The data are from the 1993 General Social Survey used in Figure 3. The additional variable is feelings about the Bible, as measured by the response to the question. 'Which of these statements comes closest to describing your feelings about the Bible?' The responses coded are 1 (Word of God), 2 (Inspired word), and 3 (Book of fables). We assume that the dependent variable is continuous (biblical absolutism vs relativism?) even though the responses are integers.

The upper plot shows error bars representing 95% confidence intervals on the means by category. Error bars are also used to represent one standard deviation or one standard error. It is important to make clear in accompanying titles or notes, which type is used. If the spacing of values on the independent variable is meaningful, then we can fit a linear regression model to our data. We shall further assume the number of sex partners to represent values of a continuous variable (promiscuity?). Assuming the assumptions for inference using a t distribution are appropriate, we can fit continuous confidence bounds on

Figure 14 Bootstrapped data from Gonnelli, S., Cepollaro, C., Montagnani, A., Monaci, G., Campagna, M.S., Franci, M.B., Gennari, C., 1996. Bone alkaline phosphatase measured with a new immunoradiometric assay in patients with metabolic bone diseases. European Journal of Clinical Investigation 26, 391–396.

the regression line as in the lower panel of the figure. This plot uses jittering to reveal the concentration of data points where they are tied.

Figure 14 shows one way to represent error by fuzziness. The data are from Gonnelli et al. (1996). They represent concentration of bone alkaline phosphatase (BAP) in a sample of women of different ages. The authors fit a linear regression (shown in the upper left panel) to argue that BAP levels increase with age.

A modal regression in the upper right panel indicates that there is a discontinuity in this relationship at age 45 years or so, corresponding most likely to the onset of menopause. Accordingly, we fit separate linear regressions to the two subgroups split at age 45 years (third panel). These regressions appear to be sensitive to outliers, however, so we fit linear models using robust regression with t weighting (fourth panel). This fit indicates that a plausible model for predicting BAP from age involves level differences but no slope differences.

It is not easy to compute confidence intervals on the robust linear fits, so we resort to bootstrapping to provide an estimate of error. The bottom panel shows the result of 20 bootstrap robust fits displayed as faint dashed lines. The non-overlapping envelopes of the fits indicates that our level-change model is reasonable.

Conclusion

Figure 15 shows the principal result of a survey by Cleveland (1984) on the use of graphics in scientific articles. The horizontal axis represents the percentage of total page area devoted to graphs in 47 articles sampled from the 1980–81 volumes of selected journals. As Cleveland noted, the substantial differences among disciplines remain when one examines number of graphs per article instead of page area.

In Cleveland's survey, social science journals ranked lowest in the use of graphics. We might speculate that this is a legacy of the aversion toward graphics among eighteenth century social scientists that Beniger and Robyn (1978) describe. Whatever the reason, there is little justification for this to continue. Software packages such as S-Plus, SAS, SPSS, and SYSTAT (used for the graphics in this article) now offer statistical graphics and publishing standards such as Adobe PDF format now make it possible to display graphics as easily as text.

Figure 15 Use of graphics in journal articles (data from Cleveland, W.S., 1984. Graphs in scientific publications. The American Statistician 38, 19–26).

Green Jobs

Olivier Deschenes, University of California Santa Barbara, Santa Barbara, CA, USA; IZA, Bonn, Germany; and National Bureau of Economic Research (NBER), Cambridge, MA, USA

Abstract

In recent years, the prospect of 'green jobs' or 'green growth' policies have become increasingly prominent, proposed to solve both the environmental challenges associated with global climate change and the persistent unemployment problems observed in many industrialized countries. This article reviews the evidence from the simulation-based studies that assess the impact of green policies on employment. Due to the sizable heterogeneity in the scope and assumptions of the existing studies, it is difficult to make a definitive conclusion about their likely impact. More careful and detailed empirical research is needed to assess the job creation potential of green job policies.

Introduction

In recent years the prospect of 'green jobs' or 'green growth' policies have become increasingly prominent, proposed to solve both the environmental challenges associated with global climate change and the persistent unemployment problems observed in many industrialized countries. In the United States, such proposals began in the Green Jobs Act of 2007 (as a component of the 2007 Energy Independence and Security Act) and continued in the American Recovery and Reinvestment Act of 2009. While the Green Jobs Act was never enacted as law, the American Recovery and Reinvestment Act of 2009 procured funding for green initiatives, primarily for energy efficiency and renewable energy investments, and for related Research and Development.

At the same time, similar policies were also proposed and implemented in many other countries, in many instances as part of broader stimulus packages. According to HSBC (2009), $430 billion (USD) in fiscal stimulus have been allocated globally to 'climate change investment themes,' with China and the United States being the two largest contributors. This corresponds to roughly 15% of global stimulus expenditures, with targeted investments primarily in low-emission transportation, grid expansion and efficiency, building energy efficiency, and renewable energy (especially in the United States for the latter).

The motivation for such targeted national investments is threefold: First, they reflect a desire by governments to stimulate the production and development of less carbon-intensive energy sources in order to reduce emissions of carbon. Second, green policies clearly have an explicit objective of boosting employment. For example, employment in sectors such as construction is expected to grow as the demand for energy-efficient homes and buildings is expected to increase as a result of these policies. Third, green policies are implemented with the expectation that they will lead to spillovers, economies of scale, and comparative advantage in the development of green technologies, and in the production of green goods and services. Consequently, these policies should be evaluated with three corresponding criteria: (1) whether they lead (or will lead) to improvement in environmental quality; (2) whether they create long-term employment and earnings growth for workers in green sectors; and (3) whether they contribute to a sustained competitive edge through learning-by-doing effects in the relevant industries. Another important criterion for evaluating targeted green policies is whether they achieve their goals in an efficient manner, relative to alternative approaches.

While many green policies are still ongoing, it is crucial to begin examining the evidence regarding the impacts of such massive investments. This short article will concentrate on the labor market impacts of green job policies. From a broader perspective, the question of whether or how green policies affect labor markets is hardly a new question. There is a long standing debate on the connection between environmental regulations and firm competitiveness, and ultimately employment. A major concern is that stricter environmental regulations lead to displacement of jobs, especially in energy-intensive and globally trading industries, although the empirical evidence regarding the magnitude of those displacement effects is mixed (see e.g., Jaffe et al., 1995; Berman and Bui, 2001; Greenstone, 2002; Walker, 2011).

The goal of this short article is threefold. First, I describe a conceptual framework to evaluate the possible employment effects of green policies. Second, I discuss the various definitional and measurement issues related to green jobs, and present descriptive evidence for the United States, based on recent data from the U.S. Bureau of Labor Statistics (BLS). Third, I review the evidence from the existing studies that attempt to assess the impact of green policies on employment. (Many of these studies also discuss possible green skills shortages associated with green growth policies. I do not address these considerations in this short article. See Bowen (2012) for a discussion of these issues.) These studies are almost entirely based on simulation models as opposed to direct empirical analysis of labor market data. Further, the majority of these studies have been published in reports as opposed to peer-reviewed journals. (An Econlit search on 'green job' reveals only two published articles in English peer-reviewed journals (accessed 25.03.13).) As a result there are substantial research gaps that need to be addressed in the coming years.

I draw two main conclusions from this exercise. First, my descriptive analysis of the U.S. BLS data on green jobs highlights that green jobs currently represent a small share of overall employment in the United States. For instance, the service sector, which accounts for half of total hours worked in the U.S.

economy is not a green sector: only 2% of employment in that sector is labeled 'green' according to the U.S. BLS definition. Published estimates from other countries also indicate that green employment only accounts for 2–3% of aggregate employment. Further, between 2001 and 2010, the share of hours worked in the 'greenest' sectors in the U.S. economy only accounted for one-third of total hours worked, and if anything the trend over time shows a slightly declining share. This very simple descriptive evidence appears to invalidate the premise that green sectors grow faster than 'brown' sectors. This premise is one of the primary justifications motivating the use of green job policies as engines of job growth and as long-term drivers of sustainable economic growth (UNEP, 2008). Thus more research needs to evaluate these claims with more rigorous empirical methods. Future research should also compare the net employment gain associated with a specific green job policy with the improvements in environmental quality it generates.

Second, due to the sizable heterogeneity in the scope and assumptions made in the existing simulation studies of the labor market impacts of green policies, it is difficult to make a definitive conclusion. This issue is only magnified by the fact that almost none of the existing studies have gone through the formal peer-review process associated with journal publications. Such process will help create and preserve continuity and progress across studies, and help streamline and homogenize the assumptions made in the simulation models. It will also better disseminate the results of this research to the economics profession. This will hopefully fuel an improved research agenda in the coming years.

In summary, much remains to be learned regarding the effect of green policies on employment creation, and whether these policies can be long-term determinants of sustainable economic growth. Further, there is little quantitative evidence on the environmental benefits associated with green job policies, and whether these benefits are sufficient to justify the costs of the green policy investments. There is a glaring lack of quality real-world microeconomic data on green jobs, and characteristics of 'green' workers. The preparation and dissemination of such data should be a priority for the relevant statistical agencies of countries investing in green growth programs.

Conceptual Framework

Targeted green policies are typically implemented through a combination of tax adjustments and publicly funded investments projects. (While obviously designed and implemented with green environmental objectives in mind, carbon-pricing policies such Europe's EU-ETS and California's AB32 are not considered as green job policies in this article.) Examples include tax credits or subsidized interest rates on loans for improving energy efficiency in buildings, various taxes, and standards promoting energy efficiency in vehicles, etc. Similarly, public funds are provided as R&D grants and subsidies for the development and generation of solar and other renewable energy, and for training programs targeted at workers in green sectors.

To begin conceptualizing the impact of such policies on labor markets, it is useful to consider the simple neoclassical labor demand model with an employment subsidy. For example, the U.S. Tax Relief and Job Creation Act of 2010 offers tax credits to manufacturers of energy-efficient dishwashers, clothes washing machines, and refrigerators, effectively reducing the costs of hiring for these firms. An employment subsidy will shift the labor demand curve in the sectors where the subsidy is granted, thus increasing both employment and wages in that sector in the short run. This effect is essentially the short-term effect described in the framework below.

Another component of the conceptual framework is the time horizon. Most existing studies consider a dynamic framework for evaluating the impacts of green policies over a varying time horizon. Sustained green policies will have effects on labor markets in the short, medium, and long run. The nature of these effects will differ over time and characterize the transition toward a less carbon-intensive economy. To illustrate this, consider this framework adapted in part from Fankhauser et al. (2008):

- *Short-term effects*: Employment grows in subsidized industries (e.g., green construction sector, low-carbon vehicle sector) and/or in sectors that produce goods and services that are complements with the green policy objectives. Employment may decline in sectors producing goods and services that are substitutes to the green policy objectives (e.g., low-efficiency vehicles). Labor and especially capital are less mobile in the short run so the possibilities of adjustment are more limited.
- *Medium-term effects*: Employment changes as the impact of the green policy diffuses through all sectors in the economy. Jobs are created and lost along the carbon-intensity dimension and due to complementarities and substitutability across sectors. (For example, a reduction in the coal-powered electricity generation could lead to reduced employment in mining and transportation industries.) Adjustments to the capital stocks begin to reflect the new economic environment.
- *Long-term effects*: Capital stocks are freely mobile. Innovation and the development of new technologies create new opportunities for investment. Net effect of targeted policies on employment attenuates over time as labor fully reallocates across sectors.

While useful as a starting point to evaluate green growth policies, this stylized framework ignores important issues that require attention. A central question not addressed is whether green jobs would emerge in the absence of governmental intervention. In other words, would consumer demand for green goods and services alone drive employment growth in these sectors? The literature remains mostly silent on this question. Another issue is whether green growth objectives could be achieved through price incentives as opposed to 'industrial policy' push, specifically by increasing the price of fossil-based energy (for example, through a carbon tax).

Regarding the transition from the short-term to the long-term effects of green policies, the main point is that the employment effects are likely to vary across the various time horizons. Employment losses are likely to be significant in carbon-intensive sectors in the short run, however, in the long run with full-labor mobility across sectors, the overall

employment effects may be null or even positive. An important question is what research methods can tell us about the short-term versus the long-term effects of green policies, and whether these policies lead to growth. While it is possible to identify the short-term effects using empirical methods, long-term effects where intersector reallocations are important will primarily be informed from model-based computable general equilibrium (CGE) analysis, although some empirical studies of long-term effects exist. (See, for example, Greenstone, 2002; Popp, 2002; Walker, 2011.)

Another important question ignored to date in the literature is whether green policy investments lead to actual improvements in environmental quality. Every job includes components of 'green' and 'brown' activity. And so the net effect of a green policy on environmental quality will depend on the types of jobs that are created and destroyed by the implementation of the policy, and on the 'green' and 'brown' nature of these jobs. A simple approach to answer this question would be to use data on carbon intensity or emissions (e.g., from life-cycle assessment models) associated with various jobs and calculate the net effect on aggregate carbon emissions of the net employment effect of a policy. As the share of green to brown jobs increases, we should expect a reduction in carbon emissions in the economy. This reduction can be monetized using estimates of the social cost of carbon (see e.g., Greenstone et al., 2011) and then compared to the size of the public investments in green job policies.

Finally, while most studies of green policies' impacts focus on employment changes as the indicator of costs or benefits associated with a policy, transitional costs associated with reallocating production and workers across sectors are likely to be significant. For example, Walker (2011, 2013) finds significant transitional costs for workers displaced by regulation implemented under the 1990 Clean Air Act Amendments. His analysis shows that 10 years after the change in regulation, employment in the impacted sectors remained 15% lower than before the change in regulation. Further, Walker also reports persistent earnings losses for workers displaced by the regulation, up to 5 years after the regulatory change, for a total earnings loss equivalent to 20% of their preregulatory earnings. Given that most studies of green job policies are based on CGE-type models that generally assume immediate reallocation, these potentially important transition costs have not been accounted for properly in the modeling literature.

Definitions and Measurement of Green Jobs

While broadly used as a notion of employment in environmentally conscious or clean energy sectors, there is no universally accepted definition of what constitutes a 'green job.' Most definitions used by statistical agencies and researchers reflect common themes, namely jobs related to the production and distribution of 'clean' energy, and to the production of environmental goods and services. Some researchers also define green jobs exclusively as the jobs created by green growth policies. Others, like the United Nations Environmental Program (UNEP), also add qualifications that green jobs must also offer adequate wages, and support workers' rights and safe working conditions.

The Green Goods and Services Survey (GGS) from the U.S. BLS considers two definitions of green jobs:

1. "Jobs in businesses that produce goods and provide services that benefit the environment or conserve natural resources," (Output-based definition).
2. "Jobs in which workers' duties involve making their establishment's production processes more environmentally friendly or use fewer natural resources," (Process-based definition).

For both definitions, the focus is on goods and services and/or production processes that relate to (1) Energy from renewable sources, (2) Energy efficiency, (3) Pollution reduction and removal, greenhouse gas reduction, and recycling and reuse, (4) Natural resource conservation, and (5) Environmental compliance, education and training, and public awareness.

Similar definitions are used in other countries. In Germany, the definition refers to "employees who produce environmental goods and services, or employees involved in environment-related activities." At the same time, other countries such as France do not have an official definition of green jobs, even though the country's statistical agency reports green employment counts. See the Supplement to the 2012 OECD Employment Outlook (OECD, 2012) for a presentation of country-specific definitions of green jobs. Based on these definitions, examples of green jobs include: manufacturing, installation, and maintenance of solar panels; production and services in sustainable agriculture, enforcement and monitoring of environmental regulations, collection and processing of recyclables, etc.

Combined with the relatively recent interest in green sector jobs, the absence of a clear definition explains why there is less data available on green jobs, except for aggregate counts. This lack of reliable microdata on characteristics of individuals working in green sectors, in turn, explains why there are no proper microeconometric studies of the employment effects of green policies.

Even after a definition of green jobs is accepted, its credible measurement remains challenging. To illustrate the problem, consider the output-based measure employed by the U.S. BLS: "jobs in businesses that produce goods and provide services that benefit the environment or conserve natural resources." The advantage of this definition is that it allows the agency to select fine industry classifications in which some or all of the employment can be considered green. The U.S. BLS then proceeds in two steps. First, the BLS has identified 333 detailed industries (6-digit NAICS, out of a possible 1192) in which green goods and services are potentially produced, after consulting with industry groups, governmental agencies, etc. (http://www.bls.gov/green/final_green_def_8242010_pub.pdf (accessed 25.03.13).) Perhaps this restriction is necessary from a practical viewpoint, but it is also a limitation of the BLS data: green goods and services are also likely to be produced in the other 859 industries.

Clearly, both green and nongreen employment will occur within and across establishments in these 333 industries. Consider the 'Commercial building construction' industry (NAICS 236220). Employment in the construction of Leadership in Energy and Environmental Design certified buildings clearly represents green employment, while employment in the

Table 1 Number and percentage of green jobs, various countries

	Number of green jobs	*Percent of total jobs 'green'*	*Data year*
Austria	162 986	3.99%	2008
Finland	5 888	0.24%	2009
France	–	1.60%	2010
Germany	–	4.50%	2006
Hungary	200 000	4.18%	2020

South Korea	604 400	2.56%	2008
Portugal	–	0.40%	2008
Spain	531 000	2.62%	2008
Switzerland	–	4.50%	2009
United States	3 100 000	2.43%	2010

Notes: Adapted from OECD, 2012. What green growth means for workers and labour market policies: an initial assessment. In: OECD, OECD Employment Outlook 2012. OECD Publishing. http://dx.doi.org/10.1787/empl_outlook-2012-5-en.

construction of standard buildings would not. To resolve this, the U.S. BLS conducts an establishment-level survey to learn about green and nongreen employment activities within establishments in a second step. (http://www.bls.gov/respondents/ggs/forms.htm (accessed 25.03.13).) Establishments participating in the survey are asked to provide a share of revenue for their green goods or services. In case of establishments with both green and nongreen employment, this revenue share was used to obtain the establishment's green employment. (In case of nonprofit or government agencies, the survey directly asks to provide a share of employment involved in the production of green goods or green services.)

Another limitation of the U.S. BLS approach of measuring the importance of green jobs is that it is based on the 2007 NAICS classifications (at least the existing 2010 U.S. BLS data is – future releases will be based on the 2012 NAICS). Any creation of new green industrial sectors post-2007 will be ignored and thus lead to undercounting. See Pollack (2012) for a more in depth discussion of the limitations of the U.S. BLS green job definition.

With these limitations in mind, it is nevertheless useful to look at the available data. **Table 1**, adapted from OECD (2012), reports the number (and percentage) of green jobs for 11 countries where such data are available. Despite slight variations in the definitions and measurement, the percentage of green jobs (relative to total employment) is fairly similar across countries, ranging from 2% to 3%. Finland has the lowest share (0.24%) and France and Germany have the highest (4.50%). The main point of **Table 1** is that green jobs account for a relatively small share of total employment in all countries where the data is available.

Table 2 examines the industrial composition, carbon intensity, and labor market importance of green jobs in the United States. The analysis is based on data from the 2010 U.S. BLS GGS, from a 2010 report by the U.S. Department of Commerce on sectoral carbon intensity, and from the individual-level data on hours worked and earnings from the 2010 American Community Survey (ACS). (Ruggles et al., 2010). The variables are linked across 27 broad industry classifications that can be linked across the different data bases. (Unfortunately, some sectors like government and public administration cannot be consistently linked across the data bases and therefore excluded from the analysis. The 27 industries considered account for 90% of the U.S. workforce.) Column (1) reports the 2008 direct carbon intensity, measured in million metric tons (mmt) of CO_2 per billion dollars (2000 USD). (The industry-specific carbon intensity measures are derived by applying CO_2 conversion factors to industry-specific energy use data. See Department of Commerce (2010) for more details.) This measure of carbon intensity provides an alternative metric of how green each sector is. In principle, data on carbon intensity could be used as a metric to compute changes in environmental quality associated with changes in employment across industrial sectors. Not surprisingly, sectors like transportation, primary metals, and nonmetallic mineral products have high carbon intensity, exceeding 1 mmt per billion (USD) of output. Across all industries, the hours-weighted average carbon intensity is 0.23. This reflects the fact that more than 50% of total hours worked in the United States in 2010 were in the relatively low-carbon intensity service sector.

Column (2) displays the BLS measure of percent green jobs (relative to total employment) in each industry. For example, these data indicate that 20% of employment in Forestry and Logging is 'green,' while essentially no jobs in Financial Activities, Education and Health Services, and Leisure and Hospitality are green. Across all industries, the hours-weighted percent of green jobs is about 3%. Further, the correlation between carbon intensity and percentage of green jobs across industries is relatively weak. It is evident that the sectors with the highest concentration of green jobs are the primary and manufacturing sectors, the sectors with the largest carbon intensity. At the same time, the concentration of green jobs in the service sector – one that accounts for roughly half of all hours worked in the U.S. economy – is relatively smaller. Nevertheless, a key point of column (2) is that it clearly establishes, at least in the United States, that green jobs are not only jobs associated with the specific sectors such as renewable energy industry (e.g., solar panel production and installation), but rather are represented in most of the major industrial sectors.

Columns (3) and (4) report the share of total hours worked and share of total wage bill (total hours worked times average hourly earnings) by industry, relative to the aggregate U.S. workforce. For both hour shares and wage bill shares, the data show a negative correlation, that is, the industries with higher concentrations of green jobs typically have lower shares of hours worked and wage bill earned. For example, primary metals has 18.5% of its employment falling under the GGS definition of the U.S. BLS, yet the sector accounts for only 0.5% of total hours worked and total wage bill in the United States in 2010. Similarly, 19.8% of employment in Forestry and Logging is green, but the sector accounts for only 0.1% of total hours worked and total wage bill in the United States in 2010. On the other hand, only 0.2% of employment in Education and Health Services contributes to the production of green goods and services, but it alone accounts for more than 25% of all hours and earnings in the U.S. economy.

Figure 1 displays the trends in the share of hours worked and total wage bill in the United States from 2001 to 2010 for

Table 2 Industrial distribution and characteristics of private sector green jobs in United States

	Carbon intensity	*Percentage of industry employment 'green' (2010)*	*Percentage of total hours worked (2010)*	*Percentage of total wage bill (2010)*

the top 50% 'greenest' industries in Table 2. (The industries with above median percent green jobs are: crop production, forestry and logging, utilities, construction, textile products, furniture and wood products, paper, nonmetallic mineral products, primary metals, machinery, appliances and electronics, transportation and warehousing, and professional, scientific, and technical services.) The trends clearly show little progress in employment and wages in these sectors during the 2000s, with both series indicating relatively constant green shares, at about 30% of aggregate hours and 32% of the aggregate wage bill. These shares also appear to dip slightly during the 2008–09 Great Recession period. This very simple descriptive evidence appears to invalidate the premise that green sectors grow faster than brown sectors. This premise underlies most of the argument for why green job policies can deliver job growth and can be long-term drivers of sustainable economic growth (UNEP, 2008). Clearly, more detailed empirical microeconomic research is needed to offer better empirical evidence and testing of the central hypotheses in green growth theory.

Review of the Existing Employment Studies

A significant number of studies, primarily based on computer simulations (CGE-type modeling) and input–output table analysis, have been conducted to evaluate the job growth potential of variously defined green job policies in Europe

Figure 1 Percentage of aggregate hours worked and total wage bill in U.S. BLS 'greenest' industries in the United States, 2001–10. Notes: Author's calculations based on 2001–2010 American Community Surveys.

and in the United States (see e.g., GHK, 2009; GCN, 2010; Bowen, 2012 for extensive reviews of this literature). Notably, few of these studies have been published in peer-reviewed academic journals. Rather, they appear as reports or working papers. For example, none of 29 studies reviewed in GHK 2009 are published in peer-reviewed journals.

Given the considerable heterogeneity in the scope and assumptions of these studies and the absence of a formal peer-review process for most existing studies, it is very difficult to draw definitive and broad conclusions. (GHK (2009) note that the employment change estimates of green policy studies are not comparable due to many factors, including difference in the consideration of gross or net employment effects, differing assumptions concerning economic growth and the effect of existing business as usual policies, etc.) In addition, studies vary greatly in the scope of policies evaluated. Some consider single renewable energy policies while others evaluate multiple policies in combination, including renewable energy targets, carbon-pricing policies, etc. Others ignore the indirect effect of green policies on job destruction in brown sectors, or other general equilibrium effects. It should be noted that these limitations are in addition those embodied in CGE analysis by construction. In the context of green job policies, an especially important limitation of CGE models is that they typically assume inelastic labor supply and free labor mobility across sectors. This implies that all adjustments occur quickly, and only through wage changes, ruling out frictional unemployment. (See Wing (2004) for a clear a discussion of the main limitations of CGE models.) It is unclear how much the combination of such assumptions leads to systematic biases in the CGE analysis.

As stated earlier, the limited availability of labor microdata with information on green jobs explains why there is no direct 'program evaluation' evidence on green job policies. In fact, there are very few empirical studies altogether. This is in contrast with the literature focusing on employment effects of carbon-pricing policies in the United States, where empirical studies and modeling studies have been successfully conducted (see e.g., Deschenes, 2012; Kahn and Mansur, 2010; Morgenstern et al., 2008).

These important limitations notwithstanding, the consensus appears to be one where green policies can deliver employment growth. In his review, Bowen (2012) also notes this and writes that taken together the evidence suggests "that climate-change policies in general and renewable energy policies in particular can generate considerable extra employment," also adding that "environmental policies will lead to substantial job creation only if other inefficiencies—including those of labor markets—are tackled."

In my view, there are too many limitations associated with the existing studies to reach a firm consensus. Conclusions such as the one presented in Bowen (2012) may turn out to be correct, but there is not enough empirical evidence to support them. Two key limitations need to be addressed before a more definitive conclusion can be reached. First, statistical agencies need to accelerate the data collection process on green jobs and provide the appropriate microdata sets to the researchers. Researchers need access to large data bases with detailed worker level information on demographic attributes, job attributes (including measures of jobs' green content), hours worked, wages, etc. This process is slowly beginning in the United States, but more countries need to follow suit.

Second, more careful and detailed empirical work is required to evaluate the job creation potential of green policies, and to inform the simulation models employed in making such assessments. In particular, more labor economists need to begin producing research in this area. The rigorous evaluation of publicly funded job training programs in the United States and Europe done by labor economists has been important in improving the design of such programs, and in developing methodological tools for evaluation (see e.g., Ashenfelter, 1978; Heckman et al., 1999). If green policies are to be successful in solving unemployment and environmental problems, the same standards of evaluation should apply to them. These empirical studies should aim to credibly document the short-run effects of green growth policies on employment, wages, unemployment duration, as well as the

transitional costs associated with labor and production reallocation.

Final Remarks and Conclusions

Massive public investments have been made and proposed to promote green growth and green jobs, yet little is known about their impacts on labor market outcomes. This reflects the lack of readily available microdata, the focus on long-term simulation analysis as opposed to program evaluation-type empirical studies, and the lack of homogeneity in the study settings and policy scenarios considered. Moving beyond labor market impacts, the improvements in environmental quality associated with green policies also need to be carefully evaluated. There remains a large agenda for future research in all of these areas.

Green Parties

Abstract

Green parties are well established in many liberal democracies. The green party family is relatively homogeneous with parties sharing common ideologies, similar origins, party structures, and constituencies of support. Electoral performance is variable – there are around 15 established successful green parties but success elsewhere is limited – and shaped by various structural factors and country-specific political opportunities. Electoral success has brought new pressures on green parties to compromise their radical policies and practices. Green parties have joined or supported government coalitions involving parties of left and right, achieving some policy impact and demonstrating that they are responsible coalition partners.

Introduction

Since their emergence in the late 1970s and early 1980s, green parties have become established political players in many industrialized democracies. Hence, today, green parties are represented in around 30 national parliaments (mostly in Western Europe), in the European Parliament, and in many more subnational and local assemblies. The German Greens are the largest and probably the most successful green party: Die Grünen first entered the federal parliament in 1983 and were sufficiently established by 1998 to form a governing red–green coalition with the Social Democrats, with Joschka Fischer assuming the roles of Foreign Minister and Vice-Chancellor for 7 years. Greens have also joined coalition governments in other European countries, including Belgium, the Czech Republic, Finland, France, Italy, and Luxembourg. In 1999, German Green Michaele Schreyer was the first green appointed to be a member of the European Commission, the European Union's (EU) powerful executive.

The steady electoral advance of the greens in advanced industrialized liberal democracies contrasts with near invisibility in the Global South, although green parties have recently secured some limited electoral successes in South America, and a smattering of greens have been elected in countries as diverse as Mongolia, Kenya, Vanuatu, Congo, and Mauritius. Moreover, electoral success brought strategic dilemmas for the greens, as they struggled to maintain their alternative 'green' credentials while entering parliaments and joining national governments. This article provides an overview of the origins, development, and current status of green parties. It examines various factors that have shaped green party electoral performance and assesses the contribution made by green parties within government coalitions and the impact of that experience on the parties themselves.

Emergence

The emergence of green parties needs to be understood in the context of the broader socioeconomic transformation of advanced industrial societies over the last 50 years that has contributed to major changes in political behavior associated with the rise of a 'new politics.' The 'old politics' consisted of frozen party systems and stable political cleavages based on class, religion, and region; political discourses were dominated by material issues such as economic growth, stable prices, unemployment, public order, national security, and the protection of traditional lifestyles. For younger, better-educated citizens in particular, the prosperity and rise in living standards enjoyed in the post-War era formed the backdrop for the emergence of new quality of life issues such as enhanced political participation, gender and racial equality, and environmental protection. Many citizens felt that these concerns were inadequately addressed by existing parliamentary structures. A proliferation of extra-parliamentary, nonpartisan citizens' movements – the new social movements (NSMs) – emerged in the 1960s and 1970s to protest about the issues of ecology, peace, nuclear power, and women's rights (Dalton, 2014).

Various explanations have been offered for this mushrooming of alternative values, issues, and forms of political behavior. Some observers identified a 'silent revolution' under way involving a shift from materialist to postmaterialist values (Inglehart, 1977). Others identified the emergence of a 'new middle class' of educated, professional service workers who were disproportionately represented in the NSMs (Cotgrove, 1982). Certainly, the massive expansion of higher education in the post-War era must have played a part. Whatever the cause, the changes in the values and forms of political activity associated with the new politics did not fit easily into the traditional left–right divide so that mainstream parties have often struggled to respond adequately to them. Yet, despite the predictions of some scholars, the new politics has not replaced the old politics, but it has disrupted and supplemented it.

However, a danger in looking to broad structural developments to explain the rise of green parties is that one critical factor in the rise of environmentalism gets ignored: the objective state of the environment. In the 1960s and 1970s, growing concern among the public was steadily heightened by continued environmental degradation and the increased media attention given to environmental issues. Toxic chemical spills in major rivers, air pollution in cities, and oil slicks in pristine coastal waters further increased public anxiety. Meanwhile, the accelerated construction of nuclear plants in the wake of the energy crisis, as well as the increased deployment of nuclear weapons, awakened or strengthened fears about the safety of

nuclear power, the problems of disposing of nuclear waste, and fears of nuclear annihilation. Subsequently, the emergence of new global problems, such as acid rain, ozone depletion, and climate change, reinforced these concerns. Thus, in searching for sophisticated social science explanations for the emergence of green parties, we should not sacrifice the most straightforward interpretation that in the 'risk society' (Beck, 1992), green politics may be fueled by a specific concern about the state of the environment, as much as it is a reflection of postmaterial values or class politics.

Whatever the explanation(s) for growing environmental concern, it is of great significance that the NSMs served as the antecedents for green parties because it meant that most green parties started out ideologically focused on new politics issues and committed to political practices that profoundly challenged conventional party politics.

The Green Party Family

Green parties make up one of only two distinct new party families to have emerged in the post-War era, the other being the radical right (Ennser, 2012). The green party family is unusually homogeneous as measured against all four common approaches to the identification of party families: party name; transnational links; origins and social base; and party policy and ideology (Mair and Mudde, 1998: p. 214–215).

First, the name of almost every party that might fall within the green party family contains the word 'Green' or a variation on 'Ecologist' (one exception is the Hungarian 'Politics Can Be Different' formed in 2009). Second, most parties belong to transnational green party federations such as the Global Greens. Membership of these transnational federations indicates that green parties see themselves as sharing common aims and principles with sister parties elsewhere. Indeed, the European Green Party even contests elections to the European Parliament on a common manifesto in every member state.

Third, the vast majority of green parties share a common ideology and program. One of the distinctive ideas underpinning green party ideology is the belief that the planet imposes limits to economic and population growth: the Earth's resources are finite and without a fundamental transformation in our economic, political, and social structures, we will exceed those limits relatively soon (Carter, 2007; Dobson, 2006). Greens offer a wholesale critique of advanced industrial society for its dependency on the inexorable pursuit of economic growth, globalization, mass consumerism, and worship of material goods. Instead, greens advocate a 'sustainable society' characterized by simpler lifestyles, less resource depletion, social equality, and local action to solve global problems. Thus, the core ideological distinctiveness of green parties rests on the priority they give to environmental issues, which underpins their rejection of the dominant growth-oriented economic paradigm and their opposition to nuclear power.

Despite this commitment to radical ecological thinking, most green parties, especially those emerging from NSM roots, were determined not to become a single-issue party. To be sure, most parties have always had factions that prioritize pure environmental policies, reject leftist ideology as too pro-industrial, and try to establish clear distance between their views and those of mainstream parties, left or right (Spoon, 2009; Talshir, 2002). Some small parties with a primarily ecological focus persist on the margins of green politics such as the Dutch De Groenen and German Ecological Democratic Party. But green party programs were typically modeled around the foundational 'four pillars' of the German Greens: ecological sustainability, grassroots democracy, social justice, and nonviolence. They adopted a range of liberal positions on social issues such as immigration, women's rights, and lifestyle choices; supported pacifist foreign policies; and took leftist positions on many core economic issues. Although frequently proclaiming that they were 'neither right nor left, but out in front,' in practice, green parties were widely regarded as left wing (often prompting the criticism from right-wing opponents that green parties resemble a watermelon – green on the outside but red on the inside). Indeed, Kitschelt (1988) characterized green parties as part of a wider left-libertarian party grouping, although this generally helpful label misses what is distinctive about green parties – their ecological orientation.

Over time, there has been considerable convergence, particularly among European green parties as a result of having formed a European green party and a common platform for European Parliament elections – gradually, those green parties opposed to EU membership as in Sweden or critical of deeper European integration as in England and Ireland have shifted to a pro-EU position. One comparative study of green party manifestos and expert survey data finds that green programs continue to prioritize environmental protection (albeit less so than in the 1980s), but they have developed a broader left-wing agenda combining radical libertarian positions with more traditional 'socialist' concerns such as expanding the welfare state and the education sector, while some of the earlier green-party priorities, such as antimilitarism and decentralization, have been downplayed, but not discarded (Carter, 2013).

The left-wing label does not so readily fit green parties outside Western Europe. One obvious anomaly is the Latvian Green Party, which has regularly contested elections with the right-wing nationalist-agrarian Farmers' Union in an alliance that has employed nationalist rhetoric and accepted significant corporate funding from the Ventspils Oil Transit Group, whose namesake is one of the oligarchs that Latvian anticorruption reformists oppose (Auers and Galbreith, 2009). The Mexican Greens (Ecological Green Party of Mexico, PVEM) have achieved some electoral success, but following their support for capital punishment, the European Greens withdrew recognition of PVEM as a legitimate green party. Subsequently, a series of homophobic statements by PVEM candidates seems to confirm that this party does not fit comfortably into the green party family.

If we exclude these maverick parties, we see that even some mainstream green parties outside Western Europe have positioned themselves differently from their longer-established sister parties. The Czech Greens achieved electoral success in 2006 by campaigning as a nonnationalistic, pro-European, center-right party, subsequently forming a right-wing coalition government with the Civic Democrats and Christian Democrats. Although the program of the Hungarian 'Politics Can be Different' is inspired by the original four pillars of the German Greens, it too is liberal on economic issues. This liberal positioning is shaped by the political context of former Soviet

bloc countries, where terms such as 'left wing' and 'socialist' often have reactionary, antidemocratic connotations that represent the very opposite of the radical and progressive politics to which green parties generally aspire. Nevertheless, the Czech, Hungarian, and also the Estonian green parties share the emphasis on environmental protection and libertarianism that is characteristic of the wider green party family. They clearly belong to the green party family, but they bring an element of heterogeneity to it.

Fourth, most green parties in Western Europe and Oceania share common origins in the NSM milieu of the 1970s and 1980s (Frankland et al., 2008; Richardson and Rootes, 1995). The broad coalition of environmental, peace, and leftist groups that formed the antinuclear movements was the catalyst for green party formation in Germany, France, Luxembourg, and Finland, and in Austria and Sweden, green parties emerged from referendum campaigns against nuclear power. Even where a green party had different origins – the first green party in the United Kingdom (originally called 'People,' later the 'Ecology Party') was formed by a group of conservative environmentalists – over time, they have taken on the characteristics of continental sister parties.

NSM activists have left a strong imprint on green parties: 'process' was critical, so the way greens expressed and pursued their beliefs was as important as the sustainable society that they were advocating. Above all, greens emphasize 'grassroots democracy': a decentralized, direct democracy within a radically participatory society. Policy decisions should be made at the lowest possible level and matched with varying local requirements. Diversity is not only tolerated but celebrated. Thus, the 'amateur-activist' organizational structure of most green parties was based on grassroots democracy, weak central organization, and a range of institutional mechanisms designed to resist the professionalization of the party, including unsalaried party officials, enforced job rotation, and collective leadership (Frankland et al., 2008). This crusade to be, in the words of Petra Kelly, an 'antiparty party' was an earnest attempt to resist the oligarchic tendencies that historically have emerged in most radical democratic parties. But green parties soon came under pressure to discard these unconventional practices, resulting in often bitter internal disagreements between social movement activists committed to the grassroots model and cadres who wanted a more 'professional' organization capable of achieving sustained electoral success. This tension was characterized by the conflicts within the German Greens between the 'fundamentalists' (*fundis*) and the 'realists' (*realos*), but it took similar forms elsewhere.

Two to three decades after their formation, green parties are undoubtedly more conventional than when they started out. Organizationally, they are much more professional and media savvy, illustrated by the willingness of some parties to sacrifice collective leadership principles in favor of a single leader (as in England and Wales and in Ireland) or to focus electoral campaigns on popular individuals such as Joschka Fischer. Yet, despite the many pressures to conform, all green parties still retain several features of the amateur-activist model. Although some of the more radical ideas such as the midterm rotation of MPs proved unworkable and were quickly dispensed with, several successful green parties (e.g., in Germany, New Zealand, and Sweden) retain a form of collective leadership with joint male and female spokespersons, while women play a prominent role and make up around half of most national green parliamentary groups. While green parties do outwardly appear more professional, the underlying party organization retains many of the amateur-activist features: rather like the mythological *centaur*, the upper part of the body has increasingly embraced a professional electoral logic, while the lower half retains its amateur-activist form (Rihoux and Frankland, 2008: p. 281).

The sociological profile of green voters and activists seems everywhere to be dominated still by members of the 'new middle class.' Dolezal's (2010) study of 12 European countries, using European Social Surveys conducted between 2002 and 2007, found that compared with supporters of other parties, greens were younger and better educated, less attached to the dominant Christian churches, and more likely to be female and an urban dweller. Dolezal identifies three categories of 'new middle class' – managers, technical experts, and 'sociocultural specialists' – and finds much higher green support among the latter. Sociocultural specialists, working outside the hierarchical structures of conventional organizations and possessing a strong orientation toward their profession and their clients, are most likely to hold libertarian values (although they are not necessarily economically left), which may draw them to the greens. Dolezal claims that there are important structural components to green voting – young, highly educated, sociocultural specialists or students, urban, and not very religious – that are connected to environmental, libertarian, and pro-immigration attitudes. Recent studies of green voters in Australia (Miragliotta, 2013), France (Beaudonnet and Vasilopoulos, 2013), and Germany (Rüdig, 2012) broadly support these demographic and attitudinal findings, although in Germany there is a 'graying' of the green voter, as habitual individual green voters have grown older.

Overall, the green party family is unusually homogeneous with most parties sharing common ideologies and programs, similar origins, party structures, and constituencies of support. However, this package has delivered variable electoral success.

Electoral Fortunes

Green parties have slowly become a stable electoral force as minor (rarely polling over 10% at national level) but serious actors in many advanced liberal democracies. They are most strongly established in Western Europe, where there is a core group of electorally 'successful' green parties. Following Müller-Rommel (1998) in defining a party as electorally successful if it contests at least two national elections and polls (on average) at least 3% of the national vote, and adding the reasonable requirement that a party is represented in a national parliament, then greens have become consistently successful in nine Western Europe countries over two decades or more: Austria, Belgium (Ecolo and Groen!), Finland, France, Germany, Luxembourg, The Netherlands, Switzerland, and Sweden. This list has been supplemented in recent years by successful green parties further afield in Australia, Canada, New Zealand, Hungary, Brazil, and Columbia (**Table 1**).

Table 1 Electoral performance of green parties in 18 countries

	First elected MP	Number of MPs[a]	Average % vote at national elections		
			1980s	1990s	2000s
Austria	1986	24	4.0	6.0	10.3
Belgium[b]	1981	12	5.9	10.9	8.0
Finland	1983	10	2.8	6.9	7.9
France	1997	17	1.1	7.2	4.5
Germany	1983	63	5.1	6.3	9.2
Ireland	1989	0	1.0	2.1	3.4
Italy	1987	0	2.5	2.7	2.1
Luxembourg	1984	6	6.8	8.9	11.7
The Netherlands	1990	4	–	5.0	5.1
Sweden	1988	24	2.9	4.3	6.0
Switzerland	1979	15	7.1	5.5	8.5
The United Kingdom	2010	1	0.3	0.5	0.9
The Czech Republic	2006	0	–	1.1	3.6
Estonia	2007	0	–	–	5.5
Hungary	2010	5	–	–	6.4
Australia	2010	1	–	2.3	7.9
Canada	1996	1	–	0.3	4.9
New Zealand	1996	14	–	6.1	7.5

Elsewhere, green parties have met limited success. Green parties have a national presence characterized by limited or sporadic electoral successes in Britain, Greece, Ireland, Italy, Norway, Spain, the Czech Republic, Estonia, and Hungary. In the United States, no green has been elected to Congress or as governor, with just a handful of representatives elected to state legislatures and in mayoral contests, although the long-standing consumer campaigner Ralph Nader secured almost three million votes when standing on a green ticket in the 2000 Presidential election. Beyond Brazil and Columbia, green party success in the Global South is very limited.

Explaining Electoral Performance

The varied electoral fortunes of green parties can be explained as a product of wider structural factors, as well as more specific opportunity structures in which these parties operate. The macroeconomic environment in which parties develop is a good starting point for explaining green party success. It is widely recognized that green parties fare better in advanced industrialized countries with high levels of economic development and a strong welfare state, especially where long-standing material affluence seems to have contributed to the rise of postmaterial values. This broad structural difference helps explain the contrast between the development of green parties in the industrialized North with their struggle to emerge and survive in the Global South. But these features are less able to explain differences among developed industrialized states: Why do green parties fare better in Germany and New Zealand than in Norway and the United States? It is helpful to turn to more specific political opportunity structures to account for such variation.

Electoral laws are often cited (especially by green parties themselves) as critical in determining success. The experience of countries such as Belgium, Finland, Germany, and Switzerland suggests that green parties do better in electoral systems based on proportional representation (PR), where there are fewer barriers to the emergence of new parties. By contrast, the plurality system used in national elections in Canada, the United States, and the United Kingdom has made it difficult for any small party to succeed unless they are regionally concentrated such as the Bloc Québécois or the Scottish National Party. The experience of New Zealand, where the green party struggled to get MPs elected under the old plurality system and then flourished when PR was introduced in the mid-1990s provides a good illustration of the key role played by electoral rules.

PR is, however, no guarantee of electoral success. Green parties have failed to make any significant electoral breakthrough in several countries with PR systems, including Denmark, Norway, Greece, and Spain. While the weakness of green parties in southern Europe may be explained partly by lower levels of economic development and the presence of fewer postmaterialists, Denmark and Norway are affluent, developed economies with high levels of public environmental concern. Conversely, the presence of greens in the French National Assembly regularly since 1997 shows that the plurality system does not pose an insuperable barrier, although this success would probably not have happened without electoral pacts with the Socialists. Recent elections have also seen individual green MPs elected in Canada and the United Kingdom. Nevertheless, on balance, a facilitative electoral system will normally be a necessary, but not a sufficient, condition for green party success.

A federal structure offers green parties more access points to articulate their demands at subnational level and more opportunities to make an electoral breakthrough, where they can gain experience and publicity. Several of the most successful green parties are in federal states (Australia, Austria, Belgium, Germany, Switzerland), although, again, the weakness of the U.S. greens shows that federal structures are no guarantee of success, while green parties have also been successful in unitary states such as Finland, New Zealand, and Sweden.

Green parties have performed comparatively well in elections to the European Parliament, where low turnouts and widespread protest voting can often reward smaller parties. Moreover, there is evidence suggesting that in elections for this supranational body the greens benefit from the public recognition that many environmental problems require international solutions. Thus, 46 green Members of European Parliament (MEPs) from 12 countries were elected in 2009, and in combination with the European Free Alliance (EFA) (a disparate group of regionalists and nationalists) they formed the fourth largest political group in the European Parliament with 55 MEPs. The number of green MEPs elected slipped slightly to 38 in 2014, but they now represented 14 countries as part of the greens–EFA group in the 2014–19 parliament.

Like other small parties, the greens benefit from those political systems that provide state funding to parties securing a certain share of the vote or number of seats as in Germany, Australia, and elsewhere. However, dependence on these funds

means that when their electoral success wanes, so does their funding: for example, after the Irish Greens dropped below 2% of the vote in 2011, the party lost all its state funding.

In addition to the impact of electoral rules and institutional features of political systems, party competition also plays an important role in green electoral success. Much depends on how green parties position themselves relative to other parties in a country's party system and how those parties respond to the presence of a green party. Most green parties have used their left-libertarian programs to locate themselves to the left of the established center-left social democratic or labor party. When many mainstream center-left parties shifted to the center ground through the 1980s and 1990s, green parties tried to colonize this vacant political territory, successfully so in West Germany, Austria, and Belgium. Sometimes, however, this political territory was already occupied, which helps explain the weakness of green parties in both Norway and Denmark, where the long-established 'left-libertarian' Socialist Left Party and Socialist People's Party, respectively, had already secured the loyalties of potential new middle-class green voters and willingly embraced a green agenda. Green parties have also encountered competition on the left from radical socialist and ex-Communist parties, such as the Swedish Left Party, the Danish Red–Green Alliance, and Syriza in Greece, who have been prepared to adopt some environmental policies. Moreover, in Scandinavia, most parties have embraced a progressive environmental agenda, so, for example, social liberal parties such as the Danish Radical Party and the Swedish Center Party have competed strongly for the environmental vote, while in Norway, the liberal Venstre and the Conservative have notably 'green' agendas. The emergence of the Swiss Green Liberals, a social liberal party outside the green party family, has harmed the electoral performance of the long-established Swiss Greens.

Green party fortunes are also shaped by the extent to which the mainstream center-left and center-right parties have been willing to share or poach the ideas of greens and adopt pro-environment policies in deed or at least in word. Typically, mainstream center-left parties have been more willing to adopt 'green' policies, presumably because they are more threatened by the rise of a left-libertarian green party than their conservative or Christian Democrat rivals. However, contemporary conservative leaders such as Chirac, Sarkozy, Merkel, and Cameron have all made attempts to present their parties as progressive and serious about the environment when they identify rising public concern about the environment that might manifest itself in support for the green party.

Episodic factors, such as environmental disasters (e.g., the Chernobyl and Fukushima nuclear calamities or major oil tanker spillages), or the rise of new controversies, such as genetically modified foods, can be the catalyst for upsurges in environmental concern. Here, green parties also face competition from other green actors, notably environmental groups or protest movements, who absorb environmental demands without themselves seeking government office. Thus, environmental awareness in the United Kingdom and the United States is not noticeably lower than in countries with strong green parties, but this concern is expressed in swelling membership of environmental groups rather than by voting for green parties.

Finally, whatever the structural constraints within which they must perform, green parties shape their own fortunes by their (in)ability to develop and articulate a coherent party platform, run a professional electoral campaign, elect popular politicians, and avoid internal combustion through infighting and personality squabbles. In short, agency matters.

Taken together, these contending explanations provide a plausible, if nuanced, explanation of green party development and change.

Greens in Government

In several countries, electoral success has brought new governmental responsibilities. The Finnish Green League in 1995 was the first green party to join a national coalition government, and by 1999, green parties were also in center-left governments in France, Germany, and Italy. Subsequently, they have provided support for minority center-left governments in Sweden, New Zealand, and Australia (and a Scottish Nationalist government) and joined rainbow coalitions in Belgium, Finland, and Luxembourg and center-right governments in the Czech Republic, Finland, and Ireland.

As the junior coalition partner, green parties have only been able to exercise limited influence over government programs (Evrard, 2012; Lees, 2000; Poguntke, 2002). Perhaps, the most notable achievements saw the German and Belgian greens push through policies for the long-term phasing out of nuclear power, although the Finnish and French greens failed in their attempts to alter nuclear policy. Green coalition governments saw the introduction of new eco-taxes and stronger conservation policies. Greens have also supported a range of liberal reforms that included giving greater protection to asylum seekers, new rights to illegal immigrants, and legal status to gay and lesbian couples. During the late 1990s, when several greens held the post of environment minister, they were able to exercise considerable influence over environmental policy within the Council of Ministers (Bomberg and Carter, 2006).

By entering parliament, the nature of internal green party debate shifted from whether they should govern to how they should govern (Poguntke, 2002). In practice, green ministers have worked civilly with their cabinet colleagues from other parties, made tough decisions, and generally demonstrated that green politicians could be trusted to hold office. But this new experience inevitably threw up many challenging dilemmas for the greens, particularly over the compromises that the realities of government required them to make. Most famously, German foreign minister, Joschka Fischer, found himself supporting military policies such as NATO air strikes on Serbia, which flouted the cherished green principle of pacifism – a decision that led to him being flour-bombed by activists. Sometimes, greens decided that it was better to resign than to compromise on a core green issue: the Finnish Greens resigned from government in 2002, when the parliament supported the construction of a new nuclear power station and the New Zealand Greens withdrew support for the labor government over its support for genetically modified crops. By contrast, the sudden resignation in April 2014 of the two EELV ministers from President Hollande's embattled Socialist government, apparently in response to its austerity measures, looked more opportunistic than principled. But most green parties have stayed the course and have not defected from the government

coalition, and where they have (e.g., Ireland), the election was fast approaching (Little, 2014). Thus, if their overall policy impact in government has been quite modest, in the longer term, green parties have demonstrated that they are a serious political force and reliable coalition partners.

The electoral impact of green involvement in government is quite varied (Little, 2014; Rüdig, 2006). Green parties in Finland, France, and Germany have not been badly punished electorally for their actions in office, and the Swedish and New Zealand greens largely escaped electoral censure for their support of minority center-left governments. But the Czech, Irish, and Dutch greens have been badly damaged. They must hope to emulate Belgium, where both the Flemish-speaking Groen! (then called Agalev) and French-speaking Ecolo were severely punished at the ballot box in 2003 after four rather ignominious years in government – but they have since recovered to previous levels of support. Either way, the internal party postmortems following their departure from office nowhere seems to have resulted in a green party deciding to return permanently to the role of protest party. Instead, the dominant response has been to make (limited) programmatic and institutional changes to enable the Greens to return to power when a suitable opportunity arises. It seems that green parties have a strong office-seeking mentality, perhaps best illustrated by the willingness of several parties to join coalitions dominated by right-wing parties.

Conclusion

The green party family is remarkably homogeneous. Most green parties continue to emphasize environmental issues while embracing a broad agenda that is left-wing on economic and social justice issues and libertarian on a range of social issues. The environmental imperative and the libertarian agenda also characterize green parties from Central and Eastern Europe, although they tend to be centrist on the left/right dimension. The recent emergence of the center-right Swiss Green Liberals is the first party of its kind in Western Europe; if replicated elsewhere, it would represent an interesting challenge to the homogeneity of the green party family.

Green parties are now not only a familiar part of the political landscape, but due to their capacity to shape party competition, government formation, and government policy, in several countries they have joined the political establishment. Although most green parties are left-wing, they are more pragmatic than in their early days (Blühdorn, 2004): having tasted power (or seen sister parties do so), greens want to make a difference, hence their willingness to work with both left-wing and right-wing parties.

Green parties face several challenges. First, how to carve out a policy niche as established parties become wiser to green demands and as ecological concerns appear more mainstream. The failure of any green party to break through the 10% barrier on a regular basis means that they are likely to remain, at best, a junior coalition partner in national government – so in seeking to influence policy, they are engaged in a careful balancing act to avoid alienating their core constituency of left-libertarian, postmaterialist voters. Second, how to take green ideas beyond the confines of rich industrialized states into Eastern Europe and the developing world, where green parties remain marginal and environmental problems acute. Third, how to ensure that the broader role of green parties – as consciousness raisers and agitators – is not sacrificed on the altar of electoral success.

Green Social Work

Abstract

Green social work is a holistic approach to social workers' involvement in ecological and environmental issues. It combines a structural analysis centered on social institutions and social relations with the duty to respond to the welfare needs of individuals, groups, and communities and care for the environment. By critiquing neoliberal capitalist models of social development and irresponsible exploitation of the earth's resources, it argues that the intergenerational interdependency between all living things and the physical environment is crucial to developing alternative sustainable models of living and being that do not conflict with the needs of the flora and fauna that share the earth with people. Solidarity built on this interdependency guarantees people's duty to care for others and the right to be looked after by them now and into the future.

Introduction

Ecosystem problems are a recent concern in social work, despite the profession's basic commitment to the 'person-in-the-environment,' which over time became limited primarily to the immediate social environment of the family and the social relationships associated with it. Ecological social work attempted to reinstate a consideration of the impact of the physical environment into social work in the early 1990s, but it was seen as a minority interest (see Park, 1996). As climate change and other ecological disasters that have affected social relationships have entered popular discourses with increasing frequency, interest in this intellectual arena has been renewed, and ecosystem concerns are becoming a growing element within the discipline.

This article discusses green social work, which differentiates itself from ecological social work (*see* Ecological Social Work: Shifting Paradigms in Environmental Practice) on several significant dimensions, and calls for the further development of this emerging part of the profession.

Defining Green Social Work

Green social work aims to promote the well-being of people and the planet's flora, fauna, and physical environment and ensure the equitable and sustainable distribution of the earth's bounty. Its vision of a more equitable, egalitarian world is rooted in a recognition of the 'politics of practice,' whereby social workers, as part of the societies they live within, have to transcend the political limitations of a normative worldview based on the inequitable distribution of the earth's resources by arguing that although this way of organizing social relations is currently dominant, this need not and should not be the case. Indeed, they argue that social development cannot continue in this vein if the world's endeavors to eliminate poverty and develop sustainable initiatives both now and in the long term are to come to fruition. In taking this approach, green social workers ground their practice in the profession's core values of human rights and social justice; an understanding of contemporary power relations and realities; and a critical theory stance toward existing dominant paradigms of education, theory, and practice in the profession.

Dominelli (2012a: p. 25) defines green social work as:

> a form of holistic professional social work practice that focuses on the: interdependencies amongst people, the social organization of relationships between people and the flora and fauna in their physical habitats; and the interactions between socio-economic and physical environmental crises and interpersonal behaviors that undermine the well-being of human beings and planet earth. It proposes to address these issues by arguing for a profound transformation in how people conceptualize the social basis of their society, their relationships with each other, living things and the inanimate world. It does so by: tackling structural inequalities including the unequal distribution of power and resources; eliminating poverty and various 'isms'; promoting global interdependencies, solidarity and egalitarian social relations; utilizing limited natural resources such as land, air, water, energy sources and minerals for the benefit of all rather than the privileged few; and protecting the earth's flora and fauna.

Consequently, green social workers seek to transform the sociopolitical and economic forces that have degraded the quality of life of poor and marginalized populations, and they demand the policy changes and social transformations needed to make this possible. The privileging of some people at the expense of others is a barrier to the right for all living things to enjoy a healthy and sustainable environment. There are 1153 billionaires enjoying the fruits of the earth and its luxuries while 3 billion people live on less than $2 per day (Kroll and Fass, 2011). These billionaires either own or manage the multinational corporations that are making decisions that impact the livelihoods and well-being of all living things through the choices they make about development options and the exploitation of natural resources and human labor power. Challenging such inequalities, which are in the main structural ones although they are experienced at the personal level, and promoting their elimination are integral ingredients in the environmental justice mix. This consideration, endorsed by those elements of the environmental movement that assert that the world's elites cannot continue with 'business as usual' or a retention of the status quo (TWN, 2012), is a component of green social work. Its practitioners address it by holding these powerful elites to account for the decisions they make and by demanding that they involve all those who are affected by their decisions in making them, to coproduce solutions to the consequences that might follow specific courses of action.

This political approach is independent of political parties, which it sees as part of the problem of governance that does not adequately protect the rights of its citizens to a healthy social development that safeguards all living things and planet earth. The centrality of this critical political approach, which questions the fundamental premises of the current organization of socioeconomic relations, differentiates green social work from ecological social work, including the 'deep ecology' movement. Moreover, this stance encompasses the whole of society and the terrain in which each person is embedded.

Additionally, green social workers use the nation-state's commitments to human rights through the Universal Declaration of Human Rights (UDHR) to argue for each person's environmental rights and the pursuit of environmental justice so that each of the earth's inhabitants can lay claim to a protected ecosystem that sustains life for the entire biosphere, which includes human beings now and into the future. This tenet is embedded in the social obligation to create a sustainable holistic environment and to maintain it, and it includes the ecosystems that their lives depend upon. In return, an individual's duty to care for others sustains his or her right to be looked after by others. This dependency upon one another becomes interdependency between people and the physical environment as well as among all peoples inhabiting planet earth. These ideals underpin the notions of solidarity and interdependency that are integral to an ethics of care that encompasses people and the physical environment within a green social worker's point of view.

All member states within the United Nations (UN) have ratified the UDHR, including Articles 22–27. These endorse people's welfare entitlements. However, each nation-state's commitment to the realization of the UDHR's principles is variable, and the UN does little to enforce compliance. The nation-state's abrogation of the responsibility to care for its peoples is a global phenomenon. The contemporary fiscal crises have further undermined these rights by demanding that individuals and families secure their own welfare needs. Countries located in the Global South plead lack of funds to legitimate their failure to provide for their citizens. Western states, especially those hard hit by the recent economic recession like Greece, Spain, and Portugal, have imposed draconian public expenditure cuts as part of an 'austerity' response that has decimated public services and hastened the loss of welfare state provisions. These cuts have brought with them political instability, a decline in social well-being, and resistance to the policies that governments have been imposing upon their peoples. Despite these protests, there has been little disruption to the dominant policy thrust that has devolved the provision of social welfare services onto individuals and families. And, although pauperization is progressing rapidly, the bankers who created these fiscal crises retain their high salaries and standards of living (Jordan and Drakeford, 2012). Part of the problem of enforcement is the UN Security Council's reluctance to trump its members' belief in the principle of the sovereignty of nations with that regarding their responsibility to care for their citizens. Thus, state violations of the duty to ensure that their citizens can secure food, clothing, shelter, education, and health services as required by the UDHR are seldom punished.

Rectifying the gross imbalances of power that this scenario represents is not easy, as the antiglobalization movements, the Occupy Wall Street Movement, and the Indignados among others have found out through their resistance to economic exigencies determining socioeconomic policies. Despite this lack of success, the vision of a better world as a realizable possibility must be retained if greater social and environmental justice is to become the norm. Green social workers promote environmental justice by resisting injustice and helping people mobilize and organize activities that protect their physical environment, promote sustainable socioeconomic development, and foster psychosocial well-being. In this sense, green social workers go beyond their civic duty of being concerned about the physical environment to conceptualize their practice as being embedded within it and being responsible for its care into the future, not just with how it is used by people in contemporary societies. Consequently, green social work practice affirms human rights and social justice to enhance the well-being of people and the environment for today and the future. Its concern to deal with forms of environmental degradation that undermine people's health and well-being provides the rationale that justifies social workers' involvement in environmental issues (Dominelli, 2011, 2012a,b).

Green social workers adopt a political stance in addressing environmental issues. They do so by recognizing that power relations shape human interactions. This includes a concern with gender, ethnicity, age, disability, and other social divisions that produce unequal outcomes for individual and collective well-being. Moreover, this approach is rooted in an ethics of care whereby people care for one another and the environment in sustainable ways to ensure that all living things will survive now and for generations to come. Green social workers are critical of the unsustainable forms of development encapsulated in contemporary neoliberal capitalist modes of production, reproduction, and consumption because these exploit the environment and people's labor and perpetuate social and environmental injustice. Green social workers' interventions are holistic, and they tackle structural forms of oppression, environmental degradation, and injustice to empower people and promote their well-being individually and collectively as well as that of planet earth. Moreover, their work intersects with and straddles the micro, meso, and macro levels of practice.

Commonalities between Ecological Social Work and Green Social Work

Social work practice has focused on the significance of the social environment as articulated through social institutions and analyzed by systems theory to define the ecological dimension of the profession. At best, its consideration of the physical environment extended to housing and transportation until recently (Shaw, 2011). Germain's (1979) edited work on this topic explicates this position comprehensively and draws attention to a range of other authors who follow this trajectory. While it shares concerns with green social work about the relationship between people and the social domain, ecological social work has traditionally ignored the impact of the wider physical environment on people's behavior except for housing and the buildings that house social institutions. This approach is currently replicated in Jack (2012).

In the United States, the concern with the physical environment, raised earlier by Park (1996), remained in the shadows until it was brought onto the agenda at a meeting of the National Association of Schools of Social Work in 2009. This was linked to sustainability and social justice in 2010, when the American educators' Council for Social Work Education produced a policy statement on the subject. A range of other initiatives followed, and Besthorn's (2002) earlier view that social work needed to be free of its focus on people as the basis of its endeavors if it were to embrace due care for the physical environment began to be openly discussed as a curriculum matter. Coates (2003) and Zapf (2009) in Canada have articulated similar points. Along with Besthorn and others, Coates sought to widen the appeal of environmental social work by incorporating the tenets of the 'deep ecology movement' into its considerations. In Europe, environmental social work became particularly strong in Belgium, where Jan Peteers (2010) and his colleagues highlighted the importance of addressing social development in sustainable terms and improving community resilience and stamina in avoiding natural disasters and responding to them. The determination to ensure sustainable social development and enhance community resilience is shared by green social work. Additionally, green social workers argue for the mainstreaming of environmental issues in research, education, and practice (Dominelli, 2012a; McKinnon, 2008).

The desire to move social work away from its anthropomorphic orientations is common to both ecological social work and green social work. Gitterman and Germain (2008) have attempted to go beyond earlier ecological writings by ascribing environmental issues to three conditions that engage practitioners in their daily work. These are crises linked to life transitions, dysfunctional interpersonal relations, and environmental pressures. While these have been integrated into the ecological model, green social work has a different stance in that it sees environmental issues as something that go beyond the life course and an individual's transitions through each separate stage. Instead, green social work views the life course as a thread that links current and future generations of people and the entire ecosphere; eschews the use of stigmatizing labels like 'dysfunctional' in referring to social relations that have gone awry; does not disassociate environmental pressures from the demands of neoliberal capitalism's profit imperative; and demands the coproduction of solutions to socio-economic and environmental catastrophes so as to engage all stakeholders. Thus, the ecological and green social work models share a concern with the 'senseless' exploitation of the earth's resources (Coates, 2003: p. 24), but the ecological approach lacks a sustained critique of neoliberal social relations and the socioeconomic and political systems associated with these. As articulated by Ungar (2002), both models are embedded in the idea that social justice cannot occur without the realization of environmental justice. Resonance between environmental justice and social justice is also crucial in the territories claimed by indigenous peoples who remain custodians of significant portions of the earth's biosphere and have waged significant struggles against environmental exploitation and the loss of attachment with the land (Hart, 2010; also *see* Indigenous Social Work).

Environmental Degradation Perpetuates Environmental Injustice

Environmental degradation perpetuates environmental injustice by making the damage and losses suffered by poor and marginalized people worse than would otherwise be the case. This damage can occur as the loss of health, life, and/or property during so-called natural disasters and human-made ones. Moreover, both poverty and inadequate social development contribute to and are caused by environmental degradation and injustice. Consequently, while 1 billion people overconsume products, 1 billion people die of hunger and a further 1 billion are malnourished. Yet, food prices have been increasing rapidly, and, in 2008, these led to riots across the globe. Additionally, 1 billion people lack clean drinking water in their homes, 2.6 billion people are without sanitation, and 1.6 billion people have no access to electricity. Furthermore, 15 million people lose their lives annually because they cannot afford drugs or access them cheaply (Newsweek, 4–11 June 2012: p. 49). Each of these factors exacerbates the hardships encountered during a disaster, regardless of its cause. Green social workers declare this situation unacceptable and work toward eliminating the inequalities that give rise to these avoidable outcomes.

These statistics are likely to get worse as environmental crises, including those initiated through climate change, increase in frequency and intensity (Oven et al., 2011). Environmental degradation can be caused by human-made disasters, including industrial pollution or malfunctioning nuclear energy plants, and/or natural disasters like tsunamis, volcanic eruptions, and earthquakes. Moreover, rising greenhouse gas emissions based on burning fossil fuels for energy and industrial production purposes are contributing to climate change. With climate change, extreme weather events associated with heat waves, cold snaps, and heavy precipitation can exacerbate the environmental damage and health problems caused by so-called natural events such as flooding and drought, which are exacerbated by inappropriate urbanization practices such as building housing on flood plains (Pearce, 2012). Today, this inequality of outcomes is evident in the figures that reveal that 76% of the damages caused by disasters are sustained in the Global South, 92% of people affected by disasters live in countries located there, and 65% of the economic losses caused by disasters are incurred in low-income countries (IFRC, 2009).

Questioning the links between industrial pollution and damage to the environment has been obvious to a number of thinkers for some time. Bullard (1987), for example, coined the term 'environmental racism' to identify and resist corporate America's use of African-American communities as dumping grounds for toxic wastes. Indigenous people have decried the destruction of pristine hinterlands in North America, South America, and Australasia because their exploitation for minerals and other commodities has left them with few jobs, fewer resources, and lost autonomy as their national governments collaborate with multinational companies based elsewhere to determine their development trajectories (Escobar, 1998). These usually disrespect indigenous peoples' priorities and concerns, thereby promoting environmental injustice. Social workers often get involved in raising consciousness about the issues and resisting these measures alongside local residents protecting their communities (Dominelli, 2012a). Moreover,

social workers are demanding a place at the table in key decision-making fora such as the climate change talks held under the auspices of the UN (Dominelli, 2011).

Environmental degradation intensifies the vulnerabilities of poor and marginalized people to disaster and its impact upon their lives and livelihoods. Increased vulnerabilities lead to increased risk, so reducing vulnerabilities becomes an important part of risk reduction strategies (RRS) and, as Peeters (2010) argues, 'sustainable' social development. The Brundtland Commission (1987) defines sustainability as "a form of development that meets the needs of the present without compromising the ability of future generations to meet their own needs," thus giving sustainability a generational twist. Social workers assist communities in formulating and implementing RRS and sustainable forms of social development. Social workers are also involved in delivering humanitarian aid to those affected by disasters and taking care of people who reach humanitarian aid camps in search of safety.

RRS are more effective if proposed activities engage people through their everyday life routines instead of being treated as special events. Involving people in making decisions about what happens in reducing risks and enhancing resilience for themselves and their communities facilitates the coproduction of knowledge and formation of partnerships that cross disciplinary divides and allow for contact between local people and subject specialists.

Green Social Work Practice

The struggle for environmental justice is an important one and focuses green social workers' activities on redressing a complex range of issues. These include the following:

- Human rights violations
- Environmental degradation
- An economic system that perpetuates structural inequalities and lacks corporate accountability
- Conflicts over the distribution of 'natural' resources
- The neglect of cultural diversity and the nonaffirmation of aboriginal and indigenous lifestyles
- Lack of people-friendly localities and supportive community relationships, especially those associated with unsustainable economic developments
- Lack of provision for health and social services that promote the well-being of people
- Lack of care for the physical environment
- Lack of recognition of the interdependency among peoples and between people and the biosphere–ecosystem
- Lack of resilient built infrastructures, resources, and communities (Dominelli, 2012a)

When working for environmental justice, practitioners uphold the duty to care for and be cared by others, including the duty to care for planet earth. In conducting these tasks, social workers (Dominelli, 2012a):

- Support people in affirming their human, social, and environmental rights
- Support people in protecting the environment, enhancing the well-being of humans and the ecosphere, and securing environmental justice
- Mobilize people in various partnerships and alliances to promote residents' and the earth's well-being
- Empower marginalized individuals, communities, and groups, especially in influencing commercial and other institutional routines as well as policy and decision-makers

Green social workers support people who are physically and psychosocially injured during disasters and assist in repairing damaged environments with the aim of facilitating longer term transformative initiatives that develop environmentally just, sustainable, life-enhancing forms of being and doing. In the course of completing these activities, green social workers carry out tasks that include:

- Assessing need
- Coordinating and delivering goods and services
- Assisting in family reunification
- Supporting individuals and communities in rebuilding their lives, developing resilience, and building capacity to minimize future risks
- Advocating, lobbying, and mobilizing for changes that safeguard the environment and prevent future disasters

Green social workers engage service users in holistic approaches that bring together people to protect their physical, social, political, economic, and cultural environments. These dimensions are part of one whole, and not separate from it. To pursue the cause of environmental justice and undertake tasks effectively, green social work practitioners ought to understand the complex power dynamics and relationships that underpin the entrenched views that people hold about their involvement in the elimination of environmental injustice. These roles, which are relevant at the individual, group, and community levels, include those of:

- Facilitator
- Coordinator
- Community mobilizer (of people and systems)
- Mobilizer of resources
- Negotiator or broker between communities and different levels of government
- Mediator between conflicting interests and groups, including gendered relations
- Consultant to government and other agencies
- Advocate for people's rights and entitlements
- Educator, giving out information about how to access relief aid and avoid diseases that can erupt following a disaster
- Trainer, particularly in how to respond effectively and in mobilizing local resources when disaster strikes
- Cultural interpreter
- Interdisciplinary translator to enable laypeople to understand scientific messages
- Therapist, helping people deal with the emotional consequences of disaster
- Protector of the ecosystem and physical environment (Dominelli, 2009, 2010, 2012a)

Given green social work's rootedness in everyday life practice, no aspect of life lies outside its remit. Moreover, its interventions involve the integration of complex understandings and diverse concerns across the social and physical terrains that green social workers articulate in their practice. These are depicted in **Figure 1**.

Practice Examples

Case Study 1: Securing Affordable Food

Tom was a green social worker concerned about the lack of fresh food among working families in an inner-city estate. Few people could afford to buy fresh fruit and vegetables. This matter was made worse by the expensive bus trip to get to a market where these items were reasonably cheap. Tom convened a meeting of interested residents, and they decided that they would try to establish a food cooperative on the estate, and that they would seek the local councilor's support in getting a plot of wasteland in the middle of the estate set aside for allotments (garden plots) so that residents could grow some of their own food to decrease reliance on the supermarkets and grow food sustainably and organically.

Tom assisted a small group of residents in discussions with farmers who were interested in supplying the cooperative with fresh fruit and vegetables at affordable prices. The farmers discovered that they could be paid more per unit of food by bringing the goods directly to the cooperative than they were able to extract from well-known supermarket chains, and the prices charged to the residents were lower than in the nearby shops. The councilor agreed to support the estate's wish to use the wasteland for allotments.

The residents' dream of having allotments proved more difficult to realize than anticipated because the large development company that owned the land was concerned that in allowing residents to use it for allotments, its plans for developing the land in future might be thwarted, especially if the government became serious about promoting 'green' initiatives of which growing one's own food could become one expression of them. The residents refused to give up. Initially, they offered to pay the company the going price for the land, but the company director refused to sell unless it were sold as land with development potential, even though he had not submitted any plans for its development.

The ensuing stalemate was shifted only when the councilor successfully convinced the company that there would be little likelihood of such permission being given for at least the foreseeable future, and challenged them to submit plans to the local council for consideration. The company refused to do this, arguing that the current economic situation mitigated against it putting forward a serious proposition. Eventually, a compromise was suggested of a sum above the current price, but with the company retaining the possibility of receiving a further amount if the land's development potential was realized. Although most of the residents were satisfied with this option, several were not. They asked Tom what could be done to protect their allotments from being taken over in the future for development purposes. Tom agreed to help them find out and took them to meet planners and lawyers for expert advice on the issues. He also found some specialists on organic farming who would provide the estate with free advice on how to grow crops sustainably. The inputs from these experts enabled the residents to put forward an alternative proposition that the company accepted.

By becoming organized, the residents had turned the issue from one about the lack of fresh food on the estate to the right to food on their terms. And, with the assistance of the green social worker, they were able to mobilize human and other resources on their estate and elsewhere to challenge a large company's definition of the land as holding future development potential that entitled them to a deferred profit. Moreover, they sought to make their gains sustainable by seeking ways of preventing the large company that had already profited by selling the land above the current market value from making further money from this deal in future by denying its interest in the matter if the land were to acquire development potential. In this way, they attempted to formulate alternative visions of the world and the relationships between them, the land, and the economic system in which they lived. To achieve this goal, the residents and Tom had to rely on expertise from several professions and obtain the support of their local representative. This indicates that green social work has to work holistically across the micro and meso levels, and engage with and navigate through competing discourses to find a solution that is acceptable to all the stakeholders involved. This case also indicates that finding local solutions to global problems – such as food insecurity, including food shortages and environmentally unfriendly forms of food production – can make a small contribution toward the development of alternatives that could be replicated elsewhere if people were to adopt them.

Case Study 2: Multilevel Interventions during Extreme Weather Events

Alice lived in a remote rural village that was prone to flooding. The villagers were a strong cohesive group that supported each other during difficult times. However, they were finding the failure of the local authority to take appropriate measures after each flooding event troublesome. In the last 5 years, their lives had been disrupted three times with major flooding requiring the evacuation of the village. Moreover, as the repairs after each event were substantial, people had barely moved back into their refurbished houses before having to leave them again and seek long-term accommodation with friends or relatives or in rented housing. A few people got so disgruntled that they left the village, and it was not long before they lost contact with friends and neighbors there.

After the third event, Alice decided that it was time that the village organized to demand that substantial flood alleviation work be undertaken. She was not sure where to look for help and support, but she talked to one of the villagers who had recently moved into the area and worked at a nearby university and asked what they could do to help. It turned out that the university had a center undertaking specific research on flooding, especially that linked to climate change, and several of the staff there agreed to help. Among this group were mathematical modelers, engineers, geographers, and

community development workers. They all attended a public meeting organized by Alice.

Jack, one of the community development workers who was interested in green issues, suggested that the local representatives for the village, the emergency planners, the fire services, and the police were also invited to attend, which they did. By having them there, Jack told Alice, they would be able to offer advice based on previous experiences of intervening in flooding situations, but they could also ensure that any proposals that came forward would get formal attention from their respective institutions and that this might result in a sustainable solution being found.

A flooding action group was formed at the meeting. Moreover, the residents made it clear that they had views about their village and what they wanted done in it, and ideas about how to minimize flooding risk that the experts from the university endorsed. The villagers were fascinated with how the mathematical modelers and geographers turned their anecdotal suggestions into models and hypotheses that could be tested through computer modeling and that these could assist policy-makers in difficult decisions when it came to prioritizing needs to make the best use of scarce resources.

After the meeting, Alice took Jack aside and informed him of how pleased she had been with the results, which included a series of further meetings to develop concrete action plans and take the matter forward. However, she said she was concerned that there had been no discussion about the links between formal carers and the informal carers who had to pick up the pieces once the emergency services departed. She added that the support of informal carers was often required for extensive periods of time, which often strained relationships between those providing informal care and those needing this help. While she did not want to discourage volunteers from coming to assist in these situations, she did not think it fair that they became the mainstay of provisions.

Jack suggested that this was an issue that could be addressed at a subsequent meeting of the flooding action group. Furthermore, he thought it also might be worthwhile to take up the issue with the local authority because it was responsible for ensuring that emergency responses were adequate for the needs of the people affected. He was sure that this matter had not been a priority in the council's earlier deliberations on flooding in the area, because he had been an observer at them, and this issue had not been raised. He also volunteered to accompany Alice and a group of residents to the council to discuss this matter if Alice organized the meeting. He suggested that the local councilor could help her set up this meeting. Alice thought this was a great idea and said she would take it forward.

As the work progressed and the long-term flood defenses began to materialize, the local media reported on the developments. The local representative later reported this work to a national meeting that Alice also attended, and it sparked national interest in the approach that the village utilized of coproducing solutions to problems. Additionally, Jack went to an international conference and gave a presentation on their work, thereby giving the initiative an international airing.

In this scenario, Alice is a villager concerned with addressing the impact of an extreme weather event – flooding in her village, which is likely to increase in frequency and intensity as a result of climate change. The multidisciplinary team, which came to assist her attempts to change the local authority's response to the villagers' desire to reduce the risk of flooding taking place and minimize the damage this might inflict, operated on a number of levels – the local, the national, and the international. Additionally, Alice raised an issue that is seldom considered in disaster interventions, including those caused by climate change – service providers' overreliance on unpaid carers for substantial periods of time, which Dominelli's (2012c) study discovered was built into the planning cycle as part of the local authorities' cost-cutting measures.

Conclusions

Environmental issues are becoming more embedded in social work education, theory, and practice. However, there is much work to be done to build on the foundations that the ecological movement, ecological social workers, and green social workers have provided. Green social workers recognize the political nature of ecological interventions that challenge the exploitation of the earth's peoples, flora, fauna, and physical ecosystems. Green social workers' analyses and actions are centered on an extensive critique of neoliberal capitalism that prioritizes profit making over the biosphere. Many vested interests will seek to condemn green social workers' involvement in ecological matters and portray their doing so as a political concern that remains outside the bounds of professional practice.

Greening of Business

John A Mathews, MGSM Macquarie University, Sydney, NSW, Australia

Abstract

The global industrial system has been amazingly successful in raising productivity and lifting incomes for hundreds of millions of people. But as it expands to come up against global limits, it gives rise to serious, if not existential, problems of which global warming is the headline case. In response, an expanding literature is contrasting two kinds of overall business trajectories, one that continues with fossil fuels and resource extraction (known as business as usual) and an alternative based on renewables and resource circulation, known as greening of business. The greening option poses a challenge for business in that it departs from the convention that business categories are considered 'content-neutral.'

Introduction

The theory and practice of global business turns on a number of widely accepted abstractions – revenues, costs, profit, inputs, outputs, efficiency, industrial dynamics, and entrepreneurial dynamics – all of which are assumed to operate without regard to underlying physical realities. The firm is held to operate in a position of 'solvency' where revenues exceed costs, and where the physical realities of these categories are not usually specified. Profit opportunities are discovered within a system of abstractions and conventions that have no direct link to the physicality of inputs and outputs. But of course the reality is that 'inputs' are always physical – in terms of certain kinds of energy and resource choices – as are outputs. Under a variety of pressures – including looming uncertainties in the supplies of these physical commodities and energy sources (or their 'peaking'), and concerns over energy and resource security – more and more firms and the countries where they are based are coming to view the underlying physical realities as being of more than passing interest.

This leads to the identification of two dominant business trends at the current time – one where the physical realities are ignored (or rather the existing fossil fuels and resource mix is assumed to continue indefinitely), termed 'business as usual' (BAU), and one where there are serious efforts made to bring business/economic activities into closer alignment with planetary boundaries and biophysical cycles. This latter is termed 'sustainable business' or 'global sustainability' (e.g., Hart and Milstein, 1999) or, more simply, 'greening of business' (GoB).

The BAU pathway is certainly the dominant trend, backed by the full weight of the global fossil fuels and resources industries together with their adjuncts and related activities such as the automotive and petrochemical industries. The majority of capital investment channeled both through the world's stock markets and the bond markets is invested in BAU activities, giving rise to a condition of 'carbon lock-in' (Unruh, 2002). The enormous productivity gains unleashed by fossil fuels and global resources extraction brought economic wealth and political dominance to the countries that first perfected this system – states such as Britain, France and ultimately Germany, the United States, and in the twentieth century, Japan – giving rise to the present drive on the part of China, India, and other emerging giants to share in the fruits of industrialization.

But as the system spreads around the globe, through the twin forces of globalization and industrialization, bringing countries such as China, India, and Brazil into the orbit of the industrialized world, so the pressures of the BAU system on the physical and ecological realities of the planet become increasingly conspicuous. These pressures are felt as resource scarcity and the 'peaking' of numerous commodities previously thought to be in near 'infinite' supply; in the growing pollution levels in air, water, and soil; in species loss and drastic reduction in biodiversity; and ultimately in global problems such as global warming that threaten extinction of the entire industrial system.

The 'greening' business variant arises as a response to these pressures and trends. It does not propose a replacement of the system of global industrial capitalism – in the way that socialism in the nineteenth and twentieth centuries proposed a socially owned alternative to the private ownership of industrial capitalism. But it does propose a radical alternative in the rules by which capitalist firms make decisions, driving their operations into closer alignment with physical and ecological realities through the operation of the financial system, fiscal system, and government regulation. While in the West, these pressures are commonly viewed as constituting a moral imperative (this is what we *should* do, to provide a legacy for our grandchildren); in China and the other emerging industrial giants, the pressure to green the economy is being viewed more as an economic imperative. The traditional 'BAU' model of industrialization simply will not scale when put into practice by the new global giants. They have to find a new and sustainable alternative – and are doing so (Hu, 2014). Whether they will do so in time is a matter that can only be subject to speculation.

In what follows the emergence of these 'greening' forces that are transforming business, and the obstacles encountered, are reviewed, and the main lines of development are traced. Note that the emphasis is on the process or trend of 'greening' and not on some putative end state of a 'green capitalism' – if such can ever be achieved.

The Nonsustainability of 'BAU'

It is the vast scale of the changes to the natural world unleashed by industrial capitalism that is the core issue for sustainability.

The workings of markets, finance, and securitization have allowed an economic system to flourish that is divorced from its ecological moorings – to the short-term benefit of all who enjoy such a system. The mode of operation, however, is probing pathologies such as 'overshoot and collapse' in one market after another – peaking of oil and other fossil fuels being the most obvious symptoms. Global warming and its consequences constitute the end result. Financialization is taking its toll (i.e., finance becoming the prime driver of business), not just in the finance sector itself but in the commodities markets as well, undermining the operation of the entire industrial system. The issue is to reestablish the system's moorings by reframing capitalism as a system embedded in an ecological matrix.

The consequences of scaling up the industrial system to its planetary limits are by now clear enough and well known in the scientific literature. The impact of humans on the terrestrial cycles of the earth is now so profound that it has spawned a new term for a new geological epoch – the *Anthropocene* (Steffen et al., 2007). Successive reviews have pointed to the seriousness of the changes unleashed – culminating in the threat and reality of global warming (Garnaut, 2008; Stern, 2007). But air and water pollution are simply the most visible of the problems created as the industrial system expands to become global. Of more immediate concern is the pressure imposed on existing supplies of fossil fuels and resources, with the prospect of political and ultimately military clashes between countries over the remaining resources. As the peak is passed in one commodity after another (particularly for conventional oil and gas) so the industry searches for more extreme resources (Klare, 2012) – meaning that they become extremely difficult to find, to produce, and entail extreme levels of danger (as evidenced in the Deepwater Horizon oil spill experienced by BP in the Gulf of Mexico in 2010). Energy security concerns, and resources security more generally, loom large as immediate problems generated by the BAU trajectory.

On top of the physical problems, there are problems facing firms that elect to continue with BAU in the form of investment in assets such as coal-fired power stations or deepwater drilling that are likely to lose value as pressure to find an alternative pathway intensifies. These 'stranded assets' that could grow to mean billions or even trillions of dollars constitute a uniquely business response to the sustainability issues raised by the existing industrial system (CTI, 2012).

Elements of Greening of Business

The main alternative to the problems created by BAU is to reestablish the industrial system's moorings by reframing of capitalism as a system embedded in an ecological matrix – calling for a new ecologic for capitalism (Mathews, 2011, 2014). This is, in essence, what is meant by the GoB. The Western model of industrial capitalism has developed through three kinds of markets. Changes are already observable in the major markets – in energy systems (from fossil fuels to renewables); in resources and commodity markets (from a linear to a circular economy); and in finance (from generic finance to eco-targeted finance). These markets are interconnected, and changes in one sector trigger changes in another, and so the process of change can be anticipated to proceed as in a chain reaction, driven by capitalist competitive dynamics.

Energy

The generation of power through harvesting renewable energy supplies constitutes a completely different energy foundation from one based on exploiting fossil fuels drilled or mined from the earth. Renewable energy sources provide a regenerative foundation for the industrial economy that calls for sophisticated technology and smart companies to develop and disseminate it; all renewable generating devices are products of manufacturing, and hence potentially available to all (Mathews and Reinert, 2014). In place of international conflict being fueled by geographical accidents where oil is found in some countries but not others, all countries will have the option of building the technologies and industries needed to harvest renewable power. China has emerged as world leader in this historic transition, creating markets, building industries, and investing in clean technologies at the maximum available rate. Renewables then emerge as the default option for the energy system of a global greening of capitalism.

Resources

There is a complementary shift under way from the *linear economy*, with its wasteful practices, to a *circular economy*. This is meant by a shift in commodity/resource flows. The prevailing economic model is based on a straight-line process starting at one end with capturing materials from nature and, at the other end, dumping the wastes again in the sink called 'nature.' But it is now known that the biosphere works according to great cycles or recirculation of materials, where wastes from one process become nutrients for another. The capitalist version of this involves eco-linkages, where one firm's waste products become another firm's inputs, and entrepreneurial activity is focused on discovering and implementing such eco-initiatives. The Chinese call this a 'circular economy' and it is already embodied in the country's 12th Five Year Plan (Mathews and Tan, 2011). The circular economy provides a template for the green economy – and the default option for the material system of a greening capitalism.

Finance

Third, there are the complementary changes in finance needed to drive through these changes in the energy and materials markets. Apart from the toxic effects of many financial derivatives, introduced without regulation and wreaking destruction, the banking and finance sector has also developed sophisticated instruments for creating credit and channeling finance to companies looking to invest in new processes. Green economy projects are looking increasingly attractive and are to be serviced by targeted finance (green banks, climate bonds). Green development projects call for high capital investment, but then have low running costs because they do not need fuel. The 'gap' between expenditure and rising income can be covered by a financial instrument such as bond, suitably

certified to ensure that funds raised are expended on a climate-friendly project. As they become adopted by institutional investors such as pension funds, these green credit instruments will aggregate projects and lower the cost of finance, thus making green economy projects even more attractive. At the last count, the OECD estimated the total as $71 trillion in pension and superannuation funds, insurance funds, hedge funds, and sovereign wealth funds (Kaminker and Stewart, 2012). If properly marshalled, these funds would transform the energy and resources world and do something serious to dent prospects of global climate change.

It is the interaction between these changes that is having the most profound effects, with each one stimulating developments in the others. The 'greening' of business is actually consistent with a worldwide trend toward living within our resource limits and makes abundant business sense – once the drivers of greening are understood. So what are the drivers of greening?

Drivers of Greening

As a business proposition, the GoB may be evaluated at different levels. At the level of individual firms, there is the prospect of new business opportunities created by greening, and the profits to be won when firms make these choices. This framing of strategic choices by firms to green their operations may be captured in the notion of 'corporate and social responsibility' (CSR) – where environmental responsibility or more broadly 'eco-responsibility' is the key idea. While it is undoubtedly the case that some firms (and some entrepreneurs, such as Elon Musk in California or Wang Chuanfu in China) have reaped substantial profits from their greening strategies, it is also the case that many firms are holding back and continuing their BAU operations in a context of carbon lock-in; these are the 'bad' and 'ugly' aspects of CSR (Devinney, 2009).

Greening initiatives clearly cover a broad span of responses, from minimal changes and those that are branded as progressive such as 'creating shared value' (Porter and Kramer, 2011; for critique see Crane et al., 2014) to genuinely comprehensive shifts in behavior and values. The 'framing' of such issues is all-important (Hoffman, 2011). A broader perspective, in which greening implies something more than an attitude on the part of firms, generates greater insight; as Siegel (2009) has argued, there has to be an objective dimension to the issue.

But the literature on greening locates broader drivers than CSR. The GoB literature today traces its origins to two important articles that appeared in the 1990s. One is the article by Hart (1997; as elaborated in Hart and Milstein, 1999) which argues that greening constitutes a trend that threatens destruction of existing industries, and greening strategies therefore represent survival choices for firms (and the planet). The other is the article by Porter and van der Linde (1995) which argued that tighter regulation on environmental matters could enhance firms' competitiveness, by forcing them to be cleaner and tighter in their management of resources (rather than simply adding to their costs, as in the conventional view). Both articles have spawned a large literature (and the Porter hypothesis in particular has been subjected to deep historical evaluation, e.g., Desrochers and Haight, in press), but as yet there has been little interaction between these two streams of work.

A way can be found to bring the two streams together, by demonstrating how they are both consistent with the greening imposed by the planetary diffusion of industrialization. In the case of Hart and Milstein, the greening pressures arise from an economic imperative (as experienced by China et al.) rather than a moral imperative as originally stated – but the emphasis on creative destruction of 'old' nongreen industries will remain. In the case of Porter and van der Linde, the regulatory pressure they were concerned with (and which has sustained a huge secondary literature, e.g., Lanoie et al., 2011) can be viewed as being generalized by the economic imperatives facing Chinese firms and driving them to change the rules of the game for everyone else. But their insistence that green pressures are procompetitive remains intact.

The strongest argument for greening of the business system is that it constitutes an economic imperative for China, India et al. as they industrialize. This puts the process of greening in the context of the diffusion of industrialization, and frames it as an economic imperative for countries such as Brazil, India and China as they seek to raise their living standards and become parties to the global business system (Spence, 2011; Hu, 2014). From this perspective the principal driver is the diffusion of industrialization to acquire a planetary scale, and the choices that this is imposing on China in the first instance, but on India, Brazil, etc. as well.

In a nutshell, China can be seen to be driving a green revolution because the country has no alternative. The transformation of China achieved over the past 30 years and more is attributed to its rapid industrialization, powered (as in all previous countries' cases) by access largely to fossil fuels and seemingly unlimited access to raw materials. But in China's case, the scale of the transformation involved means that it is rapidly becoming the primary, or largest consumer of fuels (world #1 in coal, and in imports of oil) and in this sense it is highly exposed to threats of peaking of these fuels, but more immediately to geopolitical threats and the risks of war (see e.g., Mathews and Tan, 2014). In such a setting, building up renewable energy sources as a serious and scalable alternative to fossil fuels makes abundant sense, because renewables are manufactured – and manufacturing can be managed as a domestic enterprise, unlike extraction of fossil fuels on the other side of the world and their transport through hostile waters. So there is an energy security argument for China's rapid buildup of renewables (as will be demonstrated through the data) and not just a climate change argument.

Likewise a case can be made that China cannot afford (economically, politically) to infringe too far on other countries' territory for its raw materials, and will have to develop a recycling economy as a national development priority – and this is exactly what it is doing with its circular economy developmental goal. The circular economy idea goes beyond recycling to envisage outputs of one industrial process being fed as inputs to related industrial processes – on the model of the great cycles of the biosphere – and in the case of China has been elevated to a national development goal (Mathews and Tan, 2011).

Hence it may be argued that these choices having to be made by China are driving its own industrialization and economy in a green direction, and that by capitalist competition and emulation other countries will follow suit – so that greening becomes a global trend. Germany is already the most important case in Europe (e.g., Davidson, 2012), while India and Brazil are emerging as the fastest followers among developing countries. This provides a fresh context for discussing the 'GoB' – characterized as the overall direction in which business is moving worldwide in the twenty-first century. Strategies are being fashioned for a world where renewables will be more prominent than fossil fuels, and recycling more common than virgin extraction. If these trends are sound, then 'greening' of business is in fact a survival strategy, for businesses themselves as well as for the planet.

This viewpoint provides a perspective at variance with the mainstream economics literature. One can take issue with the standard economic argument that climate policies constitute a 'cost' that represents a burden on economies (e.g., Stern, 2007; Garnaut, 2008). By contrast, it can be argued that greening is not a cost but a business opportunity – which is the appropriate perspective for the business literature. In fact greening is the biggest business opportunity of the century, given the aspirations for industrial development held by China, India, Brazil, and many more countries. Several business billionaires such as Elon Musk (Tesla), Masayoshi Son (Softbank and founder of Japan Renewable Energy Foundation), and Wang Chuanfu (BYD) already demonstrate that green issues represent an enormous business opportunity.

This business perspective spills over to an argument about policy. The economists argue that climate change calls for pricing of carbon emissions, which are perceived as a cost – whereas a business perspective would look for economic incentives to be put in place, rather than disincentives (i.e., taxes). A good example of a market-based approach to changing economic behavior is the Chinese Sloping Lands Conversion Program, where the terrible problem of loss of soil in China's river valleys has been tackled over the past decade by a program that rewards farmers for avoiding growing crops on steeply sloping land, and penalizes those who continue to do so. Feed-in tariffs likewise constitute a market-friendly incentive for the uptake of renewable energies by businesses and households, without impinging on the tax system.

In this way it may be argued that GoB is not a marginal 'add-on' for corporate strategy but can in fact be viewed as the central issue with which business will have to engage in the coming century – an engagement with energy and resources certainly, but also with water supplies (e.g., Sedlak, 2014), agriculture, construction, and almost all industrial activities. The emerging industrial economies are the primary drivers of the greening process (as opposed to other perspectives such as those that view carbon markets as drivers).

If this GoB is increasingly a worldwide phenomenon, then businesses will have to adapt their strategies to accommodate this trend – and to seek to lead it rather than just follow. In this sense, the argument is one that transcends CSR arguments. The perspective adopted engages with analyses that point to the emergence of new business models based on sustainability (e.g., Girotra and Netessine, 2013) where the emphasis is on economic imperatives rather than moral imperatives. Controversial issues abound, such as the rise of carbon markets (Dhanda and Murphy, 2011) or the rise of carbon indices on stock exchanges (Orlitzky, 2013) – all jostling for attention. These measures need to be contrasted as drivers of greening when compared with the fundamental changes driving energy and resource systems.

Transition Dynamics

The greening of markets for energy, commodities, and capital can be expected to propagate to encompass the entire economy, through multiple interfirm connections and driven by competitive forces. Green products will call for new value chains that will propagate via intermediate suppliers and aggregators back to ultimate commodity suppliers, where the greening of commodity markets will exert their effects downstream. The barriers that stand in the way of this emergent system are formidable, from the protection of vested interests and continuation of subsidies to fossil fuels, to the clash of sectional interests and the continuing financialization of markets that divorce them ever further from nature. Ultimately it is the strong states that drive fundamental change – and this was Polanyi's point in relation to the first *Great Transformation* (Mathews, 2014). It is the state intervention that creates the space where entrepreneurial initiative in building new systems can flourish. Recent work indicates, for example, the powerful role of the US state in driving enterprise and innovation, where state agencies take risks that the private sector cannot or will not accommodate (Weiss, 2014; Block and Keller, 2011) – particularly motivated by national security concerns, as in promotion of renewable energy systems by the US military. Now the role of the state in driving industrial systems onto a new, broader, greening trajectory is clear – with the case of China being the preeminent example.

From this perspective, it is clear that China's greening is already underway (as counterpart to its black development), and there is clear evidence to support this (e.g., cost reductions in solar photovoltaic industry, as demonstrated by Bazilian et al., 2013) – and that this constitutes the principal driver of greening of the economy worldwide. Basic business processes of competition and emulation will exert their effects.

As greening trends are taken up by developing countries, they can be expected to pursue the latecomer and fast-follower strategies already perfected by the East Asian countries that successfully industrialized in the twentieth century. Targets for catch-up can be identified in the renewable energy industries (Mathews et al., 2011) and in the industrial ecology initiatives now being diffused through China. It is not innovation as such that will drive this process, but market expansion and the cost reductions that follow.

Concluding Remarks

There is a dawning realization within business that the greening economy provides an alternative conceptualization of an economy that can coexist with the great ecological cycles of

nature. The kind of industrial capitalism that is emerging in the twenty-first century is one where capitalist firms operate in 'naturalized' markets, where the firm itself can grow but the system as a whole remains within its ecological limits. Boulding's image of Spaceship Earth will remain the reigning image for our time – until a new form of industrial capitalism has been put in place, one that exhibits greening trends that supersede BAU. In place of the 'content-neutral' categories of BAU capitalism, commodities are likely to carry comprehensive records of their origins (e.g., through the Internet of Things) – with future contracts on commodities markets likely to be the first instances of a new, ecologically aware industrial capitalism (Mathews, 2008). There will be growth and innovation in this system, but not the extensive growth that has characterized industrial capitalism to date. It is likely to emerge first in China because it is in China that the leadership now recognize that the promise of Western capitalism – that it could be replicated around the world – is an empty promise; this kind of 'wild capitalism' will not scale to allow billions of people to enjoy higher living standards (Nolan, 2009). And it is in China that the state is powerful enough to drive through the changes needed, backed by a commitment to sustainable enterprise as a way of legitimizing the regime. Other developing countries can be expected to emulate this Chinese model, and then the developed world itself is likely to change its ways (as is already happening in Germany and Japan). This next industrial capitalism is one that will not cost the earth. But will it appear in time? The greening of capitalism is a natural experiment whose outcome is anything but predetermined.

Abstract

Grit is a personality trait defined as passion and perseverance for long-term goals. Grit entails committing to challenging projects and working diligently toward their achievement over extremely long stretches of time. Grit predicts objectively measured achievement outcomes, including performance in the National Spelling Bee, retention at West Point military academy, and graduation from the Chicago Public Schools. Consistent with speculation by early twentieth-century psychologists that effort and talent are independent, grit demonstrates incremental predictive validity for achievement outcomes above and beyond measures of talent (e.g., general intelligence, physical aptitude), to which grit is not positively related.

Grit is passion and perseverance for long-term goals. In the face of adversity, failure, and plateaus in progress, gritty individuals hold steadfast to their commitments – not just over weeks or months, but over years and decades. With respect to the Big Five taxonomy of personality traits, grit loads most strongly on conscientiousness, a broader construct that also includes the facets of orderliness, dependability, self-control, and industriousness (Roberts et al., 2005). Like other facets of conscientiousness, grit denotes the tendency to prefer labor over leisure, to hold high standards of behavior, and to fulfill obligations rather than shirk responsibility. Unlike other facets, however, grit further denotes extreme stamina in terms of particular interests and applied effort toward these interests. Crucially, grit is not just about working hard on tasks at hand but, rather, working diligently toward the same higher-order goals for extremely long stretches of time.

The notion that sustained hard work and focused interests are distinct from talent but equally vital to success has been discussed in the psychological literature for well over a century. Perhaps in the earliest systematic inquiry into the psychological determinants of high achievement, Galton (1892) reviewed biographical information on prominent individuals in a broad array of disciplines, including science, poetry, music, art, and the law. Intellect, Galton proposed, was insufficient for eminent achievement. Rather, the most eminent individuals displayed intellect combined with 'zeal,' and the 'capacity for hard labor' (p. 38). Likewise, in a biographical study of 301 geniuses, Cox (1926) concluded that "youths who achieve eminence are characterized not only by high intellectual traits, but also by persistence of motive and effort" (p. 218). In fact, Cox speculated that persistence might be ever slightly more important: "High but not the highest intelligence combined with the greatest degree of persistence will achieve greater eminence than the highest degree of intelligence with somewhat less persistence" (p. 187). In an early review of studies on the determinants of success, Hull (1928) likewise remarked that even a person possessing the greatest natural capacity would not accomplish anything without "a certain amount of industry" (p. 185).

More recently, prospective longitudinal studies have confirmed that the personality trait of grit predicts objectively measured achievement outcomes, even when controlling for measures of talent (Duckworth et al., 2007; Duckworth and Quinn, 2009). This article discusses prior research on closely related constructs before summarizing contemporary research on grit, including known correlates and consequences, psychological antecedents, and cognitive and behavioral mechanisms. Throughout, we emphasize limitations of extant research that suggest promising directions for future research.

Prior Research on Persistence

The early twentieth century witnessed several attempts to assess persistence as a relatively stable, domain-general trait using questionnaires similar in form to those used in modern personality research. For example, under the supervision of Charles Spearman, Edward Webb (1915) studied 194 students at a teacher training institute with the aim of finding "evidence of the same person exhibiting the same characteristics generally, that is to say, under varied conditions" (p. 52). Each student was rated by two older students on 39 items, including the "degree in which he works with distant objects in view (as opposed to living 'from hand to mouth')," the 'tendency *not* to abandon tasks from mere changeability,' and the 'tendency *not* to abandon tasks in the face of obstacles.' While Webb interpreted these items to mark a single general factor of character he termed *will*, reanalysis of his data demonstrates that these items, as well as several others assessing interest in the goodness or wickedness of actions, trustworthiness, interest in religious beliefs, and the desire to excel at performances, load on a personality factor readily identifiable as Big Five conscientiousness (Deary, 1996). Subsequent researchers noted a reliable cross-sectional association between persistence ratings by informants and academic performance. For example, Hughes (1924) found that honors students were rated by their teachers as more persistent than less accomplished students, and Flemming (1925) found that teachers' ratings of high school students' persistence and their academic grades were strongly correlated.

At around the same time, psychologists began developing performance tasks to assess trait-level persistence more objectively. Typically, measurement paradigms entailed a very difficult or impossible task (or, more rarely, a facile but tedious

task) and an unlimited amount of time to work on it, with persistence indexed either as the number of attempts or the duration of voluntary engagement before giving up. Among the most extensive of these endeavors were the studies of character by Hartshorne et al. (1929), who devised physically and mentally demanding tasks to assess trait-level persistence in school-age children. For example, their Story Resistance Task brought students to the pinnacle of suspense in a written story, at which point the typeset became increasingly muddled, necessitating that students "plow through material … with capitals and small letters misplaced and words improperly spaced" (p. 329). Correlations among persistence tasks designed to be administered in groups, though small in size, were consistently positive, as were correlations between these tasks and teacher ratings of persistence. In contrast, tasks designed to be administered individually (e.g., standing on one foot for as long as possible, whistling after eating a cracker) demonstrated inconsistent associations with each other and with teacher ratings of persistence.

Several years after Hartshorne and May, Ryans (1938b) created a similar battery of physical and mental tasks for older adolescents. For instance, participants were timed on how long they could keep themselves from blinking while reading a long passage. In another task, the patellar reflex inhibition task, "the subject was informed that he should attempt to hold back or inhibit the response when…[his patellar] tendon was tapped" (p. 340). Composite scores of persistence on such tasks correlated strongly with academic success in two samples of high school students (Ryans, 1938a). Likewise, MacArthur (1955) administered a battery of persistence tasks, several borrowed from Hartshorne, May, and Maller, to adolescent boys. The underlying persistence factor accounting for positive correlations among tasks correlated moderately with academic grades ($r = 0.3$), an association that was only mildly diminished when controlling for intelligence.

By the mid-twentieth century, the study of persistence as a trait variable waned as psychologists became more interested in the study of situational influences on persistent behavior (Peterson and Seligman, 2004). More generally, the assumption that individual differences in behavior were reasonably consistent across situations came under scrutiny, with many psychologists determining that situational factors were vastly more important than traits (Funder, 2009; Mischel, 1968; Ross and Nisbett, 1991). Laboratory studies of both humans and other animals, most of which were transacted without explicit reference to earlier personality research on trait-level persistence, yielded important insights into situational factors that influence persistence (Pittenger, 2002). Among the most important of these discoveries was the partial reinforcement extinction effect (PREE), which describes the paradoxical phenomenon of increased persistence in the absence of reward after an initial training period in which behavior is rewarded intermittently, compared to a training period in which behavior is consistently rewarded (see Robbins, 1971 for a review).

More recently, Eisenberger (1992) has explained the PREE as a special case of *learned industriousness*, in which the essentially aversive sensation of effort acquires positive secondary reinforcement value by virtue of being paired with reward. For instance, Eisenberger et al. (1979) found that rats randomly assigned to a high effort, infrequent reinforcement condition (requiring the rats to shuttle up a runway five times to get a food pellet) as opposed to a low effort, frequent reinforcement condition (requiring the rats to shuttle up a runway only once to get a food pellet) showed greater persistence on a subsequent persistence task requiring a different behavior (pressing a lever for food). Similarly, Nation et al. (1979) rewarded college students on each trial or only half the trials for moving a peg back and forth; all students then experienced extinction trials in which moving the peg was not rewarded. Later, all students were asked to complete a button-pressing task in which performance was initially rewarded but, subsequently, unrewarded during extinction trials. Students who had been rewarded for only half the trials in the peg task persisted longer in the button-pressing task than students who had been rewarded on all of the peg task trials. These experimental findings, among others, led Eisenberger (1992) to speculate that stable, domain-general differences in persistence of the sort studied in Webb (1915) may originate in the extent to which individuals have experienced reward for low or high effort.

Contemporary understanding of behavior recognizes both trait-level and situation-specific determinants, a nuanced position nicely illustrated by Eisenberger's (1992) work and, indeed, augured by at least a subset of early scholars of persistence (e.g., Feather, 1962). To date, grit has primarily been studied as a relatively stable, domain-general inclination to maintain consistent, focused interest and effort for personally important and challenging goals. However, research on grit as an aspect of personality does not deny the importance of situational factors on behavior, nor does it assume that grit is entirely fixed over time. On the contrary, as detailed below, the conditions that encourage the expression of grit and its development over time constitute promising avenues for future research.

Measuring Grit

To date, most research on grit has relied on self-report questionnaires. The Grit Scale (Duckworth et al., 2007), originally containing 12 items, was later shortened to an 8-item version called the Grit-S (Duckworth and Quinn, 2009; see **Table 1**).

Table 1 Grit-S items

Grit scale
1. New ideas and projects sometimes distract me from previous ones.*
2. Setbacks do not discourage me.
3. I have been obsessed with a certain idea or project for a short time but later lost interest.*
4. I am a hard worker.
5. I often set a goal but later choose to pursue a different one.*
6. I have difficulty maintaining my focus on projects that take more than a few months to complete.*
7. I finish whatever I begin.
8. I am diligent.

Note. Starred items are reverse coded. All items are rated by participants on a scale from 1 to 5 ranging from 1 = *Not like me at all* to 5 = *Very much like me.*

Both scales demonstrate adequate psychometric properties, including internal reliability, test-retest stability, and convergent and discriminant validity (Duckworth et al., 2007; Duckworth and Quinn, 2009). An informant-report version of the Grit-S demonstrates similarly positive psychometric properties and medium-to-large associations with the self-report Grit-S (Duckworth and Quinn, 2009). Both the Grit and Grit-S scales demonstrate an oblique, two-factor structure, with half of the items describing consistency of interests over time and the other half describing sustained hard work.

Due to the well-known shortcomings of self-report measures, recent efforts have focused on developing novel ways to measure grit. One method, introduced by Robertson-Kraft and Duckworth (2012), entails coding resumes for biographical evidence of sustained commitment over time. This approach was inspired by Willingham (1985), who assessed "evidence of purposeful, continuous commitment to certain types of activities versus sporadic efforts in diverse areas" (p. 213) from high school resumes, specifically by identifying the extent to which students evinced continuous, multiyear involvement in activities and objective evidence of advancement therein. Grit ratings assigned via an analogous resume coding procedure applied to college extracurricular and work activities prospectively predicted retention and teaching performance among novice teachers 1 year later (Robertson-Kraft and Duckworth, 2012).

Correlates and Consequences of Grit

In cross-sectional research, grit has been positively associated with lifetime educational attainment among adults as well as with GPA among undergraduates at an elite university (Duckworth et al., 2007). In addition to completing more formal education, grittier individuals tend to make fewer major career changes (Duckworth et al., 2007). In large samples, grit demonstrates a monotonic, positive association with age, suggesting the possibility of normative mean-level increases in grit over the life course (Duckworth et al., 2007). However, the cross-sectional nature of such data is also consistent with cohort effects; it is possible that cultural influences more strongly encouraged grit in decades past than in contemporary society.

Stronger evidence that grit contributes to achievement comes from prospective longitudinal studies. For instance, cadets at West Point military academy completed grit questionnaires on their second day of arrival to campus; grit scores predicted which cadets would persist through the summer training, known colloquially as Beast Barracks for its exceptional rigors both mental and physical (Duckworth et al., 2007: Study 4). In contrast, a composite measure used by West Point admissions called the Whole Candidate Score, comprising a weighted average of SAT score, high school rank, ratings of leadership potential, and performance on a physical aptitude test failed to predict summer retention. Moreover, grit was not related to Whole Candidate Score or to any of its components. Nearly identical findings were obtained in two subsequent replication studies (Duckworth et al., 2007: Study 5; Duckworth and Quinn, 2009: Study 5).

Likewise, among competitors in the National Spelling Bee, grit assessed using either the Grit or Grit-S self-report questionnaires predicts superior performance in final competition months later (Duckworth et al., 2007: Study 6; Duckworth and Quinn, 2009: Study 6). Consistent with the resume coding study by Robertson-Kraft and Duckworth (2012), grittier teachers, assessed using the Grit self-report questionnaire 1 month before setting foot in the classroom, produced superior academic learning gains in their students over the course of the following school year. More recently, prospective longitudinal studies have shown that grit predicts graduation from the Chicago Public Schools, controlling for standardized achievement test scores, as well as completion of a grueling Army Special Operations course among soldiers, controlling for general intelligence and physical fitness (Eskreis-Winkler et al., manuscript in preparation).

Importantly, several studies confirm that grit predicts incremental variance for life outcomes above and beyond that predicted by Big Five conscientiousness, including educational attainment, (fewer) career changes, retention at West Point, sales job retention, and marital stability in men (Duckworth et al., 2007; Eskreis-Winkler et al., manuscript in preparation). In addition, grit is more strongly associated with the tendency to maintain a regular exercise regimen than conscientiousness (Reed et al., 2013). Collectively, both cross-sectional and longitudinal evidence point to grit as an important determinant of achievement outcomes, especially in domains where giving up is common.

Mechanisms Linking Grit to Outcomes

Why do grittier individuals excel in situations where less gritty individuals do not? To date, only two studies have identified mechanisms explaining associations between grit and achievement outcomes. The first of these studies investigated the possibility that grittier individuals dedicate more hours of deliberate practice to their chosen endeavor. Deliberate practice refers to practice activities designed to improve specific aspects of performance, performed repetitively with feedback, at levels such that challenge exceeds current skill (Ericsson et al., 1993). In a study of National Spelling Bee finalists, Duckworth et al. (2010) operationally defined deliberate practice as studying vocabulary words and word origins in solitude and distinguished these activities from being quizzed by another person, reading, and word games, which were rated by spellers as more enjoyable and less effortful than deliberate practice (Duckworth et al., 2010). Although deliberate practice was rated by all study participants as the hardest and least enjoyable form of practice, gritty contestants consistently did more of it. Moreover, hours of deliberate practice fully mediated the prospective association between grit and performance in final competition.

Counterfactual thinking is another mechanism that explains why gritty people are more likely to excel in their commitments. Counterfactual thinking refers to how individuals imagine alternatives to their present realities. Downward counterfactual thinking entails imagining a worse alternative, whereas upward counterfactual thinking entails imagining something better (Roese, 1997). In a replication study

predicting retention among cadets at West Point military academy (Kwok et al., manuscript in preparation), cadets were asked to imagine what they might be doing if they were not currently cadets at West Point. Grittier cadets, who were less likely to drop out, spontaneously imagined an alternative they rated as worse than being at West Point or reported that they could not imagine an alternative at all. By contrast, less gritty cadets, who were most likely to drop out, spontaneously imagined an alternative which they rated as better than or about the same as being a cadet at West Point. Downward counterfactual thinking fully mediated the prospective association between grit and summer retention. If replicated, this finding suggests that grittier individuals may generate lower estimates of the opportunity cost (e.g., the next best alternative) of their present commitments, thereby rendering their present commitments relatively more attractive.

Psychological Antecedents of Grit

Recent work has begun to explore the relation between grit and three motivational orientations to happiness identified by Peterson et al. (2005): pleasure, engagement, and meaning. According to this framework, individuals who pursue happiness through pleasure seek positive hedonic experiences, individuals who pursue happiness through engagement seek attention-absorbing activities, and individuals who pursue happiness through meaning seek activities that serve a greater altruistic purpose. In two samples, grittier individuals were most motivated by engagement and, next, by meaning (Von Culin et al., 2014). In contrast, grittier individuals were less likely than others to pursue happiness through pleasure, a finding consistent with the positive association between grit and deliberate practice (Duckworth et al., 2010).

Other attributes known to lead to persistence, such as optimistic explanatory style (Seligman and Schulman, 1986), provide promising avenues for future research. Optimistic explanatory style is the tendency to attribute bad events to specific, changeable causes; by contrast, pessimistic explanatory style is the tendency to attribute bad events to stable, global causes. Given that individuals with pessimistic explanatory style are less likely to persevere in the aftermath of failure (Peterson and Park, 1998; Peterson, 2000), it is unsurprising that optimistic explanatory style shows medium-sized correlations with grit, $r = 0.32$, $p < .001$ and that, in at least one study, grit statistically mediates the predictive association between optimistic explanatory style and performance (Duckworth et al., 2009). Relatedly, self-report data in a national sample of high school seniors (Duckworth, unpublished raw data) reveal a medium-sized correlation between grit and growth mind-set, the implicit belief that intellectual endowments can be improved with effort (Dweck, 2006).

Conclusion

Grit is often referred to as an exemplar 'noncognitive' characteristic, particularly in work by economists and policymakers (e.g., Almlund et al., 2011). The term noncognitive is less often used by psychologists, who recognize that all psychological processes are cognitive in the sense that they involve the brain and the processing of information (Duckworth et al., 2009). However, there is a sense in which grit is noncognitive: in most samples, grit is either orthogonal or slightly inversely related to measures of cognitive ability (Duckworth et al., 2007; Duckworth and Quinn, 2009; Eskreis-Winkler et al., 2014). Thus, the moniker 'noncognitive' is appropriately applied to grit if narrowly interpreted to denote independence from the capacity to learn. Moreover, the growing evidentiary base on grit supports earlier speculations based entirely on qualitative insights (e.g., Cox, 1926; Galton, 1892) that talent, intellectual or otherwise, is no guarantee of effort. Hence, both talent and grit would seem essential to outstanding achievement.

In 1907, William James speculated, "We are making use of only a small part of our possible mental resources…men the world over possess amounts of resource, which only exceptional individuals push to their extremes of use" (James, 1907, p. 322–323). Condemning the 'habit of inferiority to our full self,' (p. 331) James advocated that psychologists turn to explore not only the range of human abilities, but also the diverse means through which these abilities are unleashed. A little more than a century after James' pronouncement, relatively little is known about the traits that unleash the abilities in which psychology is now well versed. Research on grit has begun to address this imbalance.

Grounded Theory: Methodology and Theory Construction

Kathy Charmaz, Sonoma State University, Rohnert Park, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article focuses on the grounded theory method of qualitative analysis and outlines its strategies for theory construction. The method begins with inductive inquiry but builds a series of checks into its strategies that increase the robustness of the findings. The intellectual heritage and development of grounded theory is presented followed by a depiction of its distinctive strategies. The concluding discussion describes the current and potential contributions of this method.

Introduction

The term 'grounded theory' refers to both the product of inquiry and the method of its construction, which this article features. Grounded theory is an inductive, iterative, interactive, and comparative method that provides systematic guidelines for gathering, synthesizing, analyzing, and conceptualizing qualitative data for the purpose of theory construction.

Grounded theory begins with inductive data that the researcher analyzes from the very beginning of data collection. It is an iterative method because early analysis informs further data collection, and grounded theorists go back and forth between data collection and analysis. This strategy helps grounded theorists to refine their emerging theoretical categories through successive levels of increasingly focused data collection and analytic development. Grounded theory is an interactive method because its system of checking categories and analytic progression keeps researchers interacting with their data, emerging analyses, participants, and later, current disciplinary conversations about their topics and analytic conceptions of these topics. Throughout the whole process, grounded theory is a comparative method. Grounded theorists engage in comparing data with data, data with codes of data, codes with codes, codes with theoretical categories, and these categories with categories. When taken to its logical extension, the entire process aids the grounded theorist to move the analysis to more abstract and theoretical levels.

This article offers an explanation of the method followed by a description of its intellectual heritage. Grounded theory is the most common form of qualitative analysis that researchers identify as being used (Bryant and Charmaz, 2007). However, what constitutes a grounded theory study and which versions represent the method remain contested. The author outlines major debates about the method and presents an overview of its strategies about which researchers grounded theorists would agree with. Current emphases are presented with note of the increasing internationalization of grounded theory.

Explanation of the Method

Grounded theory assumes that researchers can construct substantive and formal theories from systematic analysis of empirical data. By beginning with inductive data and successively developing abstract concepts and their relationships, grounded theory unites data and theoretical analysis. This method consists of systematic strategies to guide qualitative inquiry, particularly, data analysis. Grounded theory favors theory construction over description, collective patterns over individual narratives, developing fresh concepts over applying received theory, and theorizing processes over assuming stable structures.

Grounded theory has two crucial characteristics that enhance its capability for theory construction: flexibility and focus. The specific strategies of grounded theory allow researchers to adapt the method to the particular exigencies of their respective research problems. Simultaneously, the method fosters sustaining increasing focus on theoretical construction. The objectives of the method include (1) demonstrating that qualitative research can generate theory, (2) explicating and providing systematic strategies for collecting and analyzing data, (3) developing a method for studying processes, and (4) democratizing the practice of theorizing. The iterative approach of grounded theory provides tools for interrogating the data with increasingly conceptual questions, correcting errors and omissions, and refining analytic ideas. Grounded theory relies on constant comparative methods. Through conducting comparisons throughout inquiry, grounded theorists can identify, explicate, and analyze the properties of their emerging categories. Grounded theory has a unique feature of providing strategies for studying basic social and social psychological processes in natural settings.

Grounded theory has gained purchase throughout many disciplines ranging from its home in sociology to moving across the social sciences. Nursing adopted grounded theory as it professionalized at the doctoral level and pursued empirical research. The method has permeated other disciplines and professions as diverse as management, education, criminology, psychology, mathematics education, cultural studies, and kinesiology. Grounded theory has produced award-winning books and noted articles in many fields in which it has been adopted.

Many researchers identify grounded theory as their analytic approach, but do most engage in theory construction? No, relatively few researchers have taken grounded theory into explicit theory construction despite numerous claims to having done so. More accurately, grounded theory has been invoked to explain conducting qualitative research. Some researchers align themselves with grounded theory because they engage in inductive inquiry. Other researchers have treated citing the method as a convenient means of legitimizing their studies. Not only has the method been poorly understood but also its

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44029-8

major proponents have disagreed about what stands as erosion or evolution of the method. Simultaneously, grounded theory has become a general method of analysis, and its strategies have been diluted and generalized as they have become routine practices in qualitative research. To further complicate this matter, meanings about what constitutes theory are varied and contested within and between disciplines. Despite some researchers' limited or superficial use of grounded theory, its strategies can help qualitative researchers increase the analytic power of their studies. Thus, this method still holds enormous potential for theory construction.

Intellectual Heritage of the Method

The founders of grounded theory, Glaser and Strauss (1967), offered the first systematic statement for analyzing qualitative data in their book, *The Discovery of Grounded Theory*. Prior to publication of their book, almost all discussions of qualitative research focused on data collection and attended to field researchers' membership roles. Grounded theory derives from the intellectual traditions of each of its founders. Strauss brought Chicago School pragmatism, symbolic interactionism, and field research to grounded theory (*see* Symbolic Interaction: Methodology; Field Observational Research in Anthropology and Sociology; Participant Observation). The writings of pragmatist philosophers impressed Strauss and permeated his mode of inquiry. Grounded theory underscored and strengthened several hallmarks of Chicago school sociology. Glaser and Strauss emphasized (1) conducting research in natural settings, (2) focusing on action and processes, and (3) assuming that actions and processes are emergent and somewhat indeterminate. In addition, Glaser and Strauss intended that grounded theory studies would offer their respective research participants a useful conceptual handle on their realities. Consistent with pragmatist notions of usefulness, Glaser and Strauss saw the potential usefulness of grounded theory research as a major contribution of the method.

Strauss's imprint on grounded theory can be found in its inductive beginnings, comparative methods, processual analyses, abductive reasoning, and emergent outcomes. In brief, grounded theorists invoke abductive reasoning to account for surprises, anomalies, or puzzles that they discover in the data. Abduction entails going back and forth between these empirical data and developing theoretical explanations of them. Abductive reasoning leads researchers to consider and test all conceivable theoretical explanations for the surprising findings. Abduction makes grounded theory more than solely an inductive method; it involves hypothesis testing as well as induction. Thus, the process of conducting research can take unanticipated directions.

Glaser's rigorous training in quantitative research at Columbia University gave grounded theory its systematic approach, positivist leanings, and procedural terms. Glaser aimed to codify steps of analysis of qualitative data in an analogous way as his mentor, Paul Lazarsfeld (Lazarsfeld and Rosenberg, 1956), had codified quantitative research. Glaser's efforts culminated in an explicit statement of how to handle data analysis (Glaser, 1978; 1998). Glaser's approach assumed a knowable world waiting to be discovered, unbiased observers, and a view of grounded theory categories as arising from the data. A cornerstone of Glaser's approach requires the researcher to avoid using preconceived theories and extant research literature to shape a grounded theory study. As a result of its divergent origins, grounded theory contains elements of both positivism and constructionism.

Grounded theory methods reflect the disciplinary arguments that had arisen in the 1950s and early 1960s. At that time, quantification had gained hegemony throughout the social sciences. Government granting agencies supported quantitative studies, and universities created research institutes for obtaining funds and pursuing quantitative research. Theory and research had become separate pursuits. The quest for quantified research findings overshadowed qualitative studies. Except for an occasional classic study, most quantitative methodologists ignored qualitative research and relegated it to disciplinary sidelines, or treated it only as a precursor to quantitative research. Quantitative researchers evaluated qualitative studies by the criteria for their research, which qualitative researchers could not meet. From these criteria, qualitative research was impressionistic, anecdotal, and idiosyncratic. Quantitative researchers often viewed the inability of their qualitative colleagues to generate verifiable facts and replicable studies as evidence of lack of rigor. Meanwhile qualitative researchers attempted to answer these criticisms by emphasizing the length of time they spent in the field, the depth of their knowledge of it, and their detailed descriptions of patterned relationships within the field.

In contrast, Glaser and Strauss (1967) argued that qualitative research had its own canons – and these must be applied to judge qualitative studies. Applying the canons of quantitative research imposed inappropriate criteria and failed to acknowledge contributions of qualitative inquiry to knowledge. Glaser and Strauss contended that qualitative research could stand as science in its own right, demonstrate rigor, and generate theory. Certainly, their works on the organization of dying buttressed these claims. Furthermore, Glaser and Strauss proposed a remarkably democratic view of theory construction by bringing it into the purview of working researchers. A sharp divide between theorists and researchers had existed in 1950s and 1960s sociology and only a few elite sociologists constructed theory. They developed theories consisting of abstract conjectures about the structure of whole societies rather than building on studies of empirical problems. Glaser and Strauss made a strong case for constructing theories that focused on the empirical world and thus linked theory and research.

Glaser and Strauss's methods appealed to social scientists who wished to conduct qualitative research but lacked tools for doing it. In the late 1960s and throughout the 1970s, grounded theory methodological rationales contributed significantly to reestablishing the legitimacy of qualitative research. This method provided researchers with ready justifications for conducting qualitative studies and strong rationales for claiming that their methodological approach was systematic. Not surprisingly, diverse qualitative researchers still claim to use grounded theory to establish their credibility and the legitimacy of their research enterprise. However, their claims of using grounded theory may rest on having adopted some form of qualitative research or on only following the initial steps of the grounded theory method.

The Discovery of Grounded Theory laid out the principles of grounded theory with remarkable success. It succeeded less as a manual for handling the concrete realities of conducting research. Glaser viewed the book as a major methodological statement; Strauss, whose lifelong connections to the discipline of sociology remained much stronger than Glaser's, appreciated its rhetorical power but was not as committed to central ideas such as entering the research as a naïve learner. Neither author foresaw the vast influence the book would have across disciplines.

Developments and Changes in the Method

With publication of Strauss's (1987) manual, *Qualitative Analysis for Social Scientists*, Glaser and Strauss's divergent directions for grounded theory began to surface. Strauss's approach maintained the inductive, iterative characteristics of their original statement but took a looser form than Glaser' (1978) had articulated in *Theoretical Sensitivity*. In this book, Glaser set forth his concept-indicator model of grounded theory and coding processes. However, the book was densely written, unindexed, and assumed prior knowledge of grounded theory that many aspiring qualitative researchers lacked. Strauss's (1987) book and his later volumes with Juliet Corbin (Strauss and Corbin, 1990; 1998) brought their version of the method to large audiences across the globe. The dual and not altogether complementary foundations of the method indicated differences from its beginnings that grew increasingly more incongruent.

Strauss and Corbin's (1990) book explicated how to conduct a grounded theory study but introduced new procedures to be applied to the research. Despite the authors' efforts to produce an accessible manual for novices, this book changed grounded theory in fundamental ways because it (1) reduced the method to procedures and thus minimized its flexibility, (2) introduced new preconceived ways of handling data that skewed the resulting analysis, and (3) deemphasized the development of emergent theoretical categories. Glaser (1992) had justifiable criticisms of the book, but his acrimonious response divided proponents of grounded theory into two camps, Glaser's objectivist method and Strauss and Corbin's postpositivist approach.

Charmaz's (2000) analysis of objectivist and constructivist grounded theory identified the positivist strains in both versions of grounded theory and proposed a new approach, constructivist grounded theory. Her approach not only builds on social constructionism of the 1970s and 1980s, but, unlike earlier forms of social constructionism, also addresses the construction of the research project and takes into account the subjectivity of the researcher as well as other research participants (*see* Constructivism/Constructionism: Methodology). Constructivist grounded theory maintains the useful methodological strategies of earlier versions of the method theory but frames them in a twenty-first century ontology and epistemology and addresses methodological developments that had occurred since the 1960s. As a result, it brought into purview relationships between the viewer and the viewed, fact and value, and the conditions of research and its products. The constructivist version treats grounded theory strategies as tools for researchers to use and adapt to fit their empirical problems. Hence, this version is less prescriptive than either earlier version of grounded theory. The constructivist revision challenges earlier notions that researchers can enter their studies uninfluenced by earlier studies and their own backgrounds and interests. The constructivist emphasis on interaction acknowledges that conceptualizations of data result from researchers' interpretive frames as well as what happens during their research and what they learn about their topics. Thus, constructivists view their analyses as emergent interpretive constructions of data rather than inhering within data.

Before the constructivist turn, grounded theorists like many qualitative researchers, had not examined their assumptions about data collection, themselves as observers and writers, and the situated nature of their studies. Adele Clarke (2005) has made these concerns central to her explication of situational analysis, which she developed to advance grounded theory. Situational analysis shares assumptions with constructivist grounded theory and builds on both Strauss's sociology and poststructuralist critiques. Before constructivist grounded theory and situational analysis, earlier grounded theorists had attempted to remain objective, neutral, and passive. They did not realize that this approach constituted a particular standpoint rather than a means of ensuring that their values remained separate from their data. Examining their own assumptions – personal and political – as well as those about the topic and research participants had not become a prerequisite for conducting grounded theory. Thus all kinds of unquestioned assumptions, such as those concerning race, gender, social class, age, and culture, along with tacit personal and professional views of the research problem and participants could enter the research.

Constructivist grounded theory and situational analysis brought new concerns into purview such as reflexivity representation of research participants, and silences into purview as central methodological considerations that have implications for substantive and formal theoretical construction. Clarke (2005) constructs ways that researchers can discover organizational silences and thus helps to move grounded theory beyond the study of individuals. Earlier grounded theory approaches had emphasized overt actions and statements rather than covert actions and implicit meanings. In recent statements about her methodological development, Juliet Corbin (Corbin, 2009; Corbin and Straus, 2008) discusses how her reexamination of method made her previous assumptions about conducting research problematic. Subsequently, she has arrived at a position in many ways consistent with that of constructivist grounded theory.

Grounded theory is gaining new spokespersons. The second generation of spokespersons for grounded theory (Morse et al., 2009) was trained by its originators, but each has adapted the method in his or her own way. For example, Phyllis Stern (2009) follows Glaserian grounded theory but brings feminist and cultural sensibilities to it. Now international researchers are joining the effort to articulate grounded theory for their colleagues. In nursing, Melanie Birks and Jane Mills (2011) offer a basic text that attends to indigenous research. In education, Robert Thornberg (2012) provides sophisticated arguments for using extant literature and advancing theoretical construction.

Conducting Grounded Theory Research

Simultaneous data collection and analysis shape grounded theory studies. Early qualitative data coding and categorizing leads grounded theorists to gather material that fits the empirical world and raises questions about it, the substantive area of inquiry and the theoretical directions of the study. By adopting Glaser's (1978) questions concerning what the data suggest that this study is about and which theoretical category a specific datum indicates, researchers begin to think theoretically about their data. Invoking analytic and theoretical questions throughout the research process focuses inquiry and gives researchers analytic leads to pursue and directions for finding data that can inform these leads.

Three major strategies of the grounded theory method are introduced here: coding, memo writing, and theoretical sampling. These strategies make grounded theory distinctive from other kinds of qualitative analysis, although they have become more diffuse and generalized as they have entered the common lexicon of qualitative inquiry. Most qualitative researchers engage in coding and memo writing but do not adopt the distinctive features of these grounded theory strategies that enable researchers to advance their work into theory construction.

Coding Qualitative Data

Grounded theorists begin coding data from the start of data collection. Original conceptions of grounded theory required researchers to avoid applying theories and ideas to their data from relevant literature. Constructivist grounded theorists view this position as untenable and naïve because both novice and seasoned researchers already have a fund of knowledge and experience. Hence, constructivist grounded theorists are less troubled by researchers being aware of ideas about the research topic before entering the field than their objectivist counterparts. However, constructivists argue that researchers must become aware of their standpoints and starting points and subject them to rigorous scrutiny.

Constructivists often begin with sensitizing concepts (Blumer, 1969). These concepts are loosely defined, general concepts, rather than those that have specific, precise definitions. Constructivist grounded theorists invoke sensitizing concepts as a beginning lens rather than a means of application. However, consistent with earlier versions of grounded theory, constructivists study their data and ask, 'What is happening here?' Researchers can use conducting line-by-line coding as a heuristic device to define what they see in their data. Using gerunds for coding helps researchers to see actions and to begin to theorize processes.

A major strength of grounded theory is that its strategies foster analyzing processes. Initial line-by-line coding also helps researchers to identify implicit meanings and actions early in the research. Charmaz (2006) advises researchers to make their codes short, simple, active, and analytic. Early line-by-line coding can enable researchers to begin conceptualizing basic processes occurring in their data by breaking bits of data into specific types of action. From studying the segments, grounded theorists may conceptualize a major process. The identification of a process allows the researcher to begin to theorize its properties and the conditions under which it develops, is maintained, and changes. Line-by-line coding gives the researcher some codes to pursue further. The researcher can use the most frequent and/or significant codes in focused coding to test whether and to what extent these codes account for large amounts of data.

Glaser (1978) first advocated line-by-line coding but more recently favors incident-by-incident coding in which he compares various incidents in the data with each other. Nonetheless, both approaches are comparative and focus on analytic development.

Memo Writing

Memo writing is an intermediate stage of writing that bridges coding data with drafting the theoretical analysis. Early memos typically begin with examination of telling codes. Grounded theorists use these codes to title their memos. Memo writing is a way for researchers to take their codes apart and study what constitutes them. Memo writing is a crucial part of the process of theoretical construction because grounded theorists define major aspects of theorizing through constant comparisons of data with other data, data with codes, codes with codes, codes with categories, and categories with categories. Memos record and preserve the comparative process and the discoveries the researcher makes from them. As researchers engage with the data and their nascent analyses, new analytic questions arise that spawn further scrutiny of data and more memos.

Throughout memo writing, researchers bring raw data into the memo and explicate how these data inform the emerging analysis. By integrating data and analysis, researchers construct sections of their reports as they proceed. Hence, they can keep fine-tuning their memos to give them greater analytic power.

Several steps move the research forward analytically. First grounded theorists define codes by their empirical properties. Distilling a code to its essential properties simultaneously condenses its description and allows the researcher to treat it analytically. Second, grounded theorists begin to ask under which conditions these properties are present or absent. Third, grounded theorists treat codes as tentative categories and interrogate their analytics significance through memo writing. Third, memo writing helps to identify gaps in the data. Subsequently the researcher can return to the field and gather the missing data. Fourth, through memo writing, researchers can ascertain the relationship between codes and categories and subsequently gain a sense of how the analytic pieces fit together. Fifth, memos also give constructivist grounded theorists a place to examine their own assumptions and implicit meanings, as well as those of their research participants. This examination may reveal liminal meanings related to the codes and tentative categories. Sixth, in addition to delineating and analyzing codes and categories, memo writing both sharpens the analysis and helps the researcher to correct problems such as making overgeneralizations and leaving his or her assertions unchecked. In short, memo writing is the field in which grounded theory discoveries germinate, take root, and grow.

Theoretical Sampling

Theoretical sampling is a pivotal part of theory construction in grounded theory but one of its most misunderstood strategies. The term confuses some researchers because the term 'sampling' ordinarily refers to specific populations that researchers intend to investigate. In contrast, theoretical sampling means sampling to develop, refine, or fill out the properties of tentative theoretical categories. Theoretical sampling makes these categories more robust and precise. What and who the researcher needs to sample cannot be known before the research begins. To engage in theoretical sampling, researchers must have a tentative category or categories. Thus, theoretical sampling follows focused coding, and researchers often discover the need for it through memo writing. Theoretical sampling simultaneously builds analytic complexity into the researcher's developing theory and keeps it grounded in data.

When engaging in theoretical sampling, researchers gather data to answer specific questions about the properties of their theoretical categories. Researchers may also use theoretical sampling to ascertain the range of variation of a category or process. Theoretical sampling increases the conceptual level of the analysis, specifies its theoretical reach, and extends its usefulness. Theoretical sampling is related to abductive reasoning. When researchers discover a surprising finding, they need to account for it. Consistent with the logic of abductive reasoning, grounded theorists attempt to entertain all possible theoretical explanations for this finding. Subsequently, they need to check and confirm the most plausible theoretical explanation for this surprising finding and thus engage in theoretical sampling.

One of the difficulties of theoretical sampling is that it can entail conducting comparisons across groups or research settings for which the researcher must justify with human subjects review committees and gatekeepers for these groups and field sites.

Theoretical sampling allows researchers to 'saturate' their theoretical categories. Saturation occurs when researchers find no new properties of these categories. At this point grounded theorists stop collecting data. The definition of saturation leaves ample room for claims-making among researchers as the criteria for saturated properties is at best ambiguous. However, saturation of theoretical categories involves a considerably more exacting engagement with data and theoretical construction than saturation of themes or data, with which it is sometimes confused. In the latter case, researchers report that same themes reoccur, or research participants report similar views and experiences. This type of saturation contrasts with the saturation in grounded theory that researchers accomplish through theoretical sampling.

Current Emphases and Future Directions

Over the past decade, four emphases have emerged that bode well for further developments in grounded theory. First, the method continues to make major contributions to qualitative research in the social sciences and beyond. The constructivist and postpositivist versions of grounded theory have earned credibility across the globe, which recent translations of their key works have buttressed. Their major spokespersons view their versions as having distinctive grounded theory characteristics but as complementing and extending trends in qualitative research. In addition, both these versions acknowledge the symbolic interactionist and pragmatist roots of the method and the legacy of Anselm Strauss. Protagonists of objectivist grounded theory, in contrast, treat the origins and development of the method as wholly Glaserian and emphasize their differences from constructivist and postpositivist grounded theory – as well as from qualitative inquiry.

Second, renewed interest in pragmatism and the symbolic interactionist underpinnings of grounded theory have sparked new discussions of the role of abduction in the method. As more researchers aim toward theory construction, engaging in abductive reasoning becomes a crucial element in constructing fresh theoretical analyses of the studied empirical problems. The most helpful way to use abduction is to expand the range of theoretical possibilities and subsequently confirm which hypothesis offers the best theoretical account for the data. However, grounded theorists must not let the existing range of theories inhibit constructing new theories or initiating new directions of inquiry.

Third, grounded theory is taking an increasingly significant role in mixed methods research. Grounded theory methods fit both the logic and practice of mixed methods. Until recently, the definition of mixed methods assumed that studies included both qualitative and quantitative components. A mixed methods study may be driven by either component, although quantitatively driven studies are the most common. In both types of studies, methods are likely to be added rather than mixed in actual research practice. For quantitatively driven studies, grounded theory can offer ways to (1) fine-tune instrument design; (2) check quantitative findings; (3) deepen empirical knowledge; (4) address participants' views and experiences; (5) provide a conceptual framework for the study, as well as meeting such practical concerns to improve clinical trials; (6) identify and reduce investigator biases; and (7) fulfill funding agencies' goals. In qualitatively driven grounded theory studies, the method has always fostered gathering the kinds of data pertinent to the research problem and the merging questions it raises, although few grounded theorists have defined themselves as mixed methods researchers.

Fourth, the constructivist turn has supported research in social justice. The constructivist emphasis on language and meaning heightens awareness of different definitions and the resulting actions such definitions encourage. Similarly the constructivist awareness of multiplicity of perspectives and multiple realities sensitizes grounded theorists to look beyond the surface and to study what happens among diverse research participants. All these concerns fit researching the effects of ideologies, hierarchies, and uses of power. Grounded theorists are poised to construct useful theories in social justice inquiry that offer conceptual handles on specific issues and may generate persuasive changes in policy arenas.

Last, the constructivist turn placed grounded theory on new epistemological and ontological foundations. It also developed a clear statement of grounded theory strategies that preserves the original grounded theory emphasis on emergent theory construction. Grounded theory has always focused on analytic

strategies. Now Charmaz (in press) addresses data collection and its implications for developing grounded theory studies. This direction will help new and seasoned researchers to integrate all aspects of their developing grounded theory studies. Such efforts are likely to be taken up by other researchers who see the advantages of grounded theory strategies and wish to contribute to strengthening them.

This article is a revision of the previous edition article by D. Frey, F. Brodbeck, volume 9, pp. 6407–6413, © 2001, Elsevier Ltd.

Abstract

The article refers to group processes as they influence organizational functioning. The main features of groups (e.g., norms, cohesion, roles), and factors contributing to their performance are characterized. We detail well-established concepts like groupthink and social identity theory. Further, we refer to important current topics in organizational practice and research related to group functioning, like team mental models, diversity in groups, and counterproductive work behavior. Finally, hints at the practical relevance in terms of the implementation of these concepts in organizational contexts are provided (e.g., organizational change, leadership in multinational corporations, and shared leadership).

General Introduction

Success and failure in organizations depend not only on individual knowledge, skills, and abilities but also on the quality of the interaction and communication within and between organizational groups. Group processes are intertwined with many parameters at individual levels (e.g., motivation and commitment) and organizational levels (e.g., mergers and acquisitions, and error prevention). Group processes are therefore of high relevance to organizational functioning. Moreover, the study of groups is a central subject of social psychology as well as organizational psychology. During the 100-year history of group research, a substantial amount of literature has been amassed. In the following, we concentrate on a selection of topics, which we believe are of particular relevance to the understanding of group processes in organizations. The topics are in part traditional and long established, and in part innovative and future-oriented.

Definition and Structural Dimensions of Groups

Groups are defined as a number of individuals who are oriented toward the same or similar goals and who interact and communicate in order to achieve these goals. All groups share at least three structural principles: norms and values, a certain degree of cohesion, and role differentiation.

Norms and Values

Norms can be defined as the shared expectations of group members about how to act in certain situations. Values comprise a set of shared beliefs, which represent the ethical ideals of the group, like interpersonal fairness and openness. Both norms and values guide the behavior of group members, make their behavior more predictable, and thus help to clarify social relationships.

Degree of Cohesion

When group membership is highly attractive – because individuals assume that goal achievement and need satisfaction are more likely in the group than individually – group members are motivated to sustain their contact with the group. The sum of all forces that increase group attractiveness is called cohesion.

Role and Status

Role differentiation in groups is the social-psychological basis for joint work. Roles are defined as the expectations of group members about appropriate behavior in a certain position. Role-conformant behavior is sanctioned positively, whereas role deviation is sanctioned negatively. Status means that group members differ in the hierarchy of prestige, power, influence, and privileges. High-status group members as compared to low-status group members experience fewer restrictions when attempting to deviate from group norms (idiosyncrasy credit).

Conformity and Dissent

Conformity and dissent are central to group functioning and goal achievement. Behaving in accordance with group norms is required to interact at low levels of conflict. Usually, group pressure aligns group members' behaviors and attitudes with group norms, which can be functional for goal achievement. However, normative behavior can also be dysfunctional, as has been shown by Solomon Asch's (1951) studies in which group members expressed clearly wrong and irrational perceptions due to group pressure toward conformity.

Groupthink

Groupthink describes the phenomenon by which existing information that is relevant to a certain decision is not processed by group members in a rational and systematic way. Instead, information processing is biased in the direction of a preferred decision alternative within the group. This bias increases the risk of faulty decisions. Analyzing historical political disasters following group decisions, such as the American invasion of Cuba, Janis (1982) specified symptoms of groupthink: (1) Illusions of invulnerability; that is, high

conformity of group members' views and thinking styles makes them overconfident. (2) Willingness to take high risks leads group members to not take negative feedback seriously; that is, group members avoid questioning their own basic beliefs when facing a challenging decision. (3) Stereotyping of members with a different opinion by labeling them as incompetent. (4) Pressure toward conformity exerted by the formal leader or the majority of the group; that is, subsequent self-censorship processes make group members (falsely) assume that silence means approval. The risk of groupthink is amplified when groups are homogeneous (see Diversity in Groups), when group structures are markedly hierarchical, and when a strong commitment to particular decision alternatives exists before group discussion begins. Considerable empirical evidence deals with prevention and intervention strategies to counteract groupthink (for an overview see Frey et al., 1996). For example, effects of groupthink are reduced if (1) the group leader acts as an impartial coordinator, (2) self-confident minority members are encouraged to speak up, (3) opinions of external experts are integrated into the group decision, (4) artificial conflict is implemented in the group decision process (e.g., devil's advocacy or dialectical inquiry techniques), (5) each group member is held individually responsible for the decision process and its outcome, and (6) different subgroups are created to separately engage in decision making. Symptoms and consequences of groupthink are observable in many applied contexts, such as work in project teams or decision making on organizational boards. Therefore, the concept of groupthink has been frequently applied to explain corporate or political failure (e.g., accounting fraud; Scharff, 2005).

Team Mental Models

Team mental models are defined as organized mental representations, which group members share about key elements in their environment (for an overview see Mohammed et al., 2010). These mental representations refer to task-related contents (i.e., which tasks need to be completed) as well as team-related contents (i.e., how task completion is best achieved through cooperation). Two major aspects further characterize team mental models: (1) their similarity among group members and (2) their accuracy. High levels of similarity imply that group members hold compatible mental models, which in turn results in common expectations for task completion and interpersonal cooperation. Accuracy of team mental models is defined by the degree to which shared knowledge and belief structures reflect existing conditions in the organizational environment. Team mental models have been studied predominantly under the assumption that they contribute to organizational effectiveness. However, overly shared knowledge and belief structures may result in phenomena comparable to groupthink (see Groupthink) when group members oppose revising outdated or incorrect mental models because the group shares them.

Minority Influence

Conformity and homogeneity in groups may come at the expense of divergent thinking. Due to conformity pressure, the default information processing style in groups is consent oriented. Minority influence, however, often generates productive dissent. According to Moscovici (1976), minority members are able to oppose the pressure toward conformity in groups under certain conditions – and are thereby able to influence attitudes and behaviors of the majority. In doing so, minority members are required to present their point of view in a consistent manner, though not rigidly, while signaling their willingness to compromise. Thereby, minority members trigger an internal cognitive conflict for majority members. This conflict in turn leads to majority members' intensified information processing and is accompanied by an increase in divergent and creative thinking styles, less biased information search, and greater openness for the minority position. In contrast, majorities exert a pressure to conform, which produces social conflict between individual group members or subgroups rather than cognitive conflict. This pressure leads to more superficial processing of information and is accompanied by conventional and conformist styles of thinking. Minority influence in organizations is a precondition for scrutinizing common patterns of thought and practice, and thus represents an important condition to organizational learning, change, and innovation. Recent research shows that the impact of minority opinions in organizations is significantly moderated by motivational and structural factors, like social motives and decision rules underlying negotiations (e.g., Velden et al., 2007).

Diversity in Groups

Diversity is defined as an actual or perceived difference in salient attributes of a given group. Work groups have become increasingly diverse over the last decades: The retirement age went up in several countries, more women engage in full-time jobs, and individuals from different countries are often part of the same work group. Groups with diverse members offer advantages, but also face more difficulties than work groups composed of members who are similar to each other.

Gains and Losses of Diversity

In their thorough review of 40 years of diversity research, Williams and O'Reilly (1998) discuss the impact of demographic diversity on group processes and performance. They present three main theoretical perspectives: (1) The similarity/attraction paradigm; that is, similarity between individuals fosters social attraction. Hence, groups with similar members will collaborate better than groups with diverse members. (2) The social categorization perspective; if individuals in a group are different or perceive themselves to be different from other group members, categorization will occur. The subsequent formation of subgroups will lead to more conflict and less cohesion. However, following the (3) information/decision-making perspective, heterogeneous groups will integrate diverse perspectives, experiences, and task-relevant information, which in turn enhance creativity and task performance. Overall, as research shows, if and when diversity leads to desired outcomes is significantly influenced by contextual variables and diversity dimensions (for an overview see van Knippenberg and Schippers, 2007).

Diversity Dimensions

Group members may differ from each other on several dimensions. The most prominent dimensions are group tenure, age, educational background, gender, and ethnicity. In work groups with high tenure diversity, members with either lowest or highest tenure as compared to other group members are more likely than others to leave the group, often because they experience more group conflict. Hence, these group members will take their knowledge, skills, and experiences along. In contrast, age diversity is hardly associated with an increase of relationship conflict within the group, but can still have negative consequences for turnover. Furthermore, groups that consist of members with functionally diverse educational backgrounds experience more conflict about the task at hand than homogeneous groups. However, this type of conflict as compared to relationship conflict eventually leads to better problem solving. When group members are diverse in terms of gender, it depends on the proportion of men and women in the group whether gender diversity leads to positive or negative performance results: In groups with high numbers of men and only few women, group outcomes are generally lower than in gender homogeneous groups. Yet, the presence of few women in top positions paves the way for the advancement of other women to leadership positions. In groups with comparable numbers of men and women, and in groups with many women and few men, diversity does generally not lead to negative team outcomes. Ethnic diversity has similar effects: When there is a clear minority, ethnic diversity will lead to more conflict or turnover. However, when the group is very heterogeneous, the salience of differences in ethnicity diminishes and group performance increases. In addition to demographic diversity, so-called deep-level differences of group members, such as diversity in values or work motivation, become pivotal for group outcomes over time. When group members work together for a longer period of time, their deep-level diversity leads to negative performance outcomes, whereas the impact of demographic diversity wears off.

Creativity and Innovation

In many cases, diversity is not advantageous for groups when they need to solve simple and routine tasks. However, diversity is beneficial when innovation and creativity are required for problem solving because members of heterogeneous groups are more likely to engage in in-depth information processing (see Minority Influence). Moreover, when group members hold positive as compared to negative beliefs about diversity as well as when they *perceive* themselves to be similar to each other, diversity is more likely to lead to desired outcomes (Hentschel et al., 2013). Thus, organizations are required to emphasize a culture that values its diverse work force when striving for creativity and innovation. Constructive communication in heterogeneous groups is another important factor to stimulate creativity. Open-mindedness toward diverging opinions and experiences enhances innovation, idea transfer, and continuous optimization in groups. West (2002) describes group members' need to experience a feeling of psychological safety to express diverse views. Additionally, he specifies the importance of managing task conflict adequately and reflecting on team processes, goals, and strategies as major parameters to advancing innovation. Team reflection serves to raise group members' awareness of their group's strength as well as weaknesses and potential for improvement. Behaviors of the group's leader are also of high importance: Clear goals and supervisory support are profitable for idea generation, whereas too much control impedes creative thinking.

Integration of Individual Contributions

Organizational successes rely heavily on group performance, that is, the integration of individual contributions in a way such that production losses (e.g., uncoordinated action, demotivation, interpersonal conflict) are minimized and procedural gains or synergies (e.g., transfer of motivation, mutual learning, knowledge sharing) are maximized. Theory and research on group performance have undergone significant developments, leading to new trends like research on team mental models, collective emotions, and group faultlines in addition to traditional predictors of group performance (for an overview see Kerr and Tindale, 2004). We first address the concept of synergy in groups, then turn to antecedents of high-level group performance, and shed light on counteracting influences.

Synergy in Groups

The term group synergy suggests that a group is more than the sum of its parts, or more precisely, that a given group generally performs better than its most talented single member. Yet, Stroebe et al. (1992) argued that the common belief in group synergy is grounded in individuals' tendency to overestimate their success in group contexts. For example, where brainstorming is concerned, individuals usually believe that they are more productive when working in groups – probably because they feel 'enriched' by the ideas of others. However, individual group members are inclined to claim other group members' ideas as their own body of thought and, hence, to overestimate their own contribution. Yet, other phenomena have been described in the literature, which speak in favor of process gains and group synergy rather than process losses in groups. First, group learning will occur over time, if several individuals work interactively on the same task. That is, skills and knowledge will be transferred between individual group members, from individuals to the group, and vice versa, as well as at the group level. Second, joint problem solving in groups holds the potential for motivation gains through social competition (i.e., group members seeking to outperform each other), social compensation (i.e., stronger group members compensating for weaker group members' performance), or increased feelings of responsibility (e.g., weaker group members working harder than they would do individually to avoid being held responsible for a weak group performance, the so-called Köhler Effect). Third, initial dissent reduces the probability that group members prematurely agree on suboptimal decisions because conflicting opinions intensify and 'debias' discussions about existing, but hidden information. Overall, synergy in groups requires systematic activities of group performance management (for details, see Schulz-Hardt and Brodbeck, 2012).

Group Performance and Type of Task

A common approach to evaluate group performance is to compare actual group performance to potential group performance (or group potential). Group potential is the performance that would have occurred if the members of a group had worked individually on a given task. When actual group performance diverges from group potential, this is due to process losses and process gains. This relationship is expressed in the following formula (Hackman and Morris, 1975): Actual group performance = group potential − process losses + process gains. In order to determine whether and to what extent a group is working below, above, or at its full potential, actual group performance must be obtained and compared to the potential level of performance. The difference reflects the extent to which group-induced process gains and losses have occurred.

Further, different types of group tasks have been distinguished (Steiner, 1972), which hold significant implications for group potential. The structure of a task may be additive, in which case the potential group performance is the sum of all individual performances, for example, in brainstorming. If a task is structured in a conjunctive way, it requires all group members to be successful for the group to complete the task. In this case, the group potential is determined by the individual performance of the group's weakest member, for example, when climbing a mountain in a rope team. If a task is disjunctive, the group has to decide on one particular solution to a problem. The group potential is the result of the best individual performance, for example, in mathematical calculations.

Top Performance and Organizational Culture

Despite antagonistic forces such as conformity, groupthink, and motivation or coordination losses, top performance in organizations does occur. In particular, organizational cultures of excellence promote top performance based on the following values (Peus and Frey, 2009):

- Problem solving for continuous learning and improvement, for instance, through self- and other-reflection (i.e., what is good and should be sustained, what is bad and should be improved)
- Mistakes as learning opportunities with an orientation toward best practice ideas and benchmarking (i.e., comparing the group with best practices in the organization, in the branch, with national and international competitors)
- Constructive confrontation and conflict solving (i.e., the demand for and encouragement of thinking outside the box, constructive stubbornness, speaking up)
- High commitment to excellent and innovative output (i.e., rules and regulations are minimized, and the organization is willing to take risks in order to motivate visionary thinking)

The homogeneity in norms, values, and assumptions creates organizational cultures, which enable the systematic integration of individual contributions from group members equipped with a diverse set of talents, experiences, and educational backgrounds (Schein, 1990).

Counterproductive Work Behavior

As opposed to the factors just presented, certain aspects in groups significantly hinder organizational performance, among them partly involuntary actions like the inability to detect and correct human errors, and but also deliberately harmful behavior in organizational settings.

With regard to counterproductive work behavior (CWB), O'Boyle et al. (2011) proposed an integrative multilevel model of individual, group, and organizational antecedents based on a review of earlier theory and research. CWB captures a wide range of deliberate actions that harm the organization (e.g., theft, sabotage) or its members (e.g., bullying) by undermining interpersonal relationships and performance. These actions may vary in severity as well as underlying motivation (e.g., anger, revenge, narcissism). With reference to work groups, the following predictors of CWB are suggested:

- Supervision (e.g., abusive or laissez-faire)
- Group norms (e.g., acceptance of drinking at work or absenteeism)
- Group processes (e.g., relational conflicts resulting in hostile atmosphere)
- Dissimilarity (e.g., dissimilar moral values resulting in reduced compliance to ethical norms)

Due to the severe consequences of CWB for organizational functioning, it is advisable for practitioners and researchers alike not only to focus on the presence or absence of positive predictors for group performance but also to detect active detrimental influences.

Group Dynamics

Interaction in organizational groups is significantly shaped by the development of interpersonal relationships and roles. Such dynamic processes haven been considered from different theoretical perspectives. First, from the perspective of socioemotional relations, cohesion, role formation, communication, and building of trust are relevant. Linear models predict the development of socioemotional relations in groups over time. Second, from a perspective of goal-directed and output-oriented group actions, goal setting, role differentiation, leadership, decision making, and problem solving are necessary for positive group dynamics. In the following, we present stages of group development, which are related to both, interpersonal and task characteristics, and introduce central concepts related to intragroup conflicts as well as group processes in intercultural settings.

Group Stages

Typically, groups in organizations undergo several phases of development from their initial formation to a joint functioning. Established models propose five stages of group development (Tuckman and Jensen, 1977):

- Forming: Group members discover norms of interpersonal behavior and structures of interdependence, and identify their group tasks.
- Storming: Intragroup conflict arises because group members express their individuality and resist formation of stable group structures.

- Norming: Individuals accept group membership, and group cohesion develops. The group becomes an entity protected by the development of group norms. Task conflicts are avoided in favor of group harmony.
- Performing: Interpersonal relationships have been established, and the group has developed into a problem-solving unit. Members take over specific roles to enhance the group's task functioning, and to solve task-related problems.
- Adjourning: As a project terminates, dissolution of the group takes place, wherein tasks are completed, roles are given up, and interdependence of group members is reduced.

A more recent model by Hackman and Wageman (2005) proposes three group stages along a task cycle from its beginnings (i.e., the group launch), to the midpoints (i.e., after making first experiences with group and task), and to the ends (i.e., when the task or relevant subtasks have been accomplished). The model posits that coaching interventions adapted to each of these stages will enhance team effectiveness. Effort-related (motivational) interventions apply at the beginning, strategy-related (consultative) interventions are effective near the midpoint, and (educational) interventions, which address knowledge, skills, and lessons learned, apply at the end of a task cycle.

Intragroup Conflicts

In early stages of theory and research, conflicts in groups have been described as detrimental to organizational functioning. Yet, within the last decades, the field of intragroup conflict has developed considerably, such that it is now providing more comprehensive insights into the different types of conflict and their consequences (for an overview see De Wit et al., 2012). The underlying goal of this string of research is to identify conditions under which intragroup conflict is destructive or productive, and to derive recommendations for improved organizational functioning. While relationship conflict in groups generally decreases satisfaction and performance, task conflict holds advantages for performance on nonroutine tasks. As this finding indicates, not only the type of conflict but also the type of task at hand is crucial for the impact of intragroup conflict. In the face of task conflict, group members engage in deeper and more deliberate information processing. For complex, nonroutine tasks, such critical thinking processes lead to enhanced creativity and effective problem solving. In contrast, for routine tasks with established procedures, task conflict is rather detrimental to performance because it interferes with existing routines. Overall, the negative picture of intragroup conflict has shifted. Therefore, organizations are advised to design and structure collaboration in work groups in a way such that relationship conflict between group members decreases, but that task conflict informs decision making and problem solving.

Culture and Group Dynamics

Since globalized work settings are more and more common, it is important to understand intercultural group processes and their impact on group dynamics. For example, group members' surface-level dissimilarity, which is in part shaped by ethnic diversity, holds the potential to negatively influence group dynamics (e.g., social integration in groups), which in turn relates to outcomes of work groups in organizations (Guillaume et al., 2012). Further, certain conditions moderate these relationships, like interdependence in groups or perspectives toward cultural diversity at work. That is, intercultural group processes can contribute positively to group dynamics and outcomes when cultural diversity is interpreted as a resource for learning and change. In contrast, intercultural group processes can also entail risk of within-group alignment. Group faultlines are formed when group members split up into subgroups based on individual attributes (e.g., race, ethnicity). Group faultlines have been shown to affect group dynamics (e.g., relationship and task conflict, cohesion), and to explain variance above and beyond the effects of team diversity on group outcomes (for an overview see Thatcher and Patel, 2011). Finally, according to group members' cultural orientations and value preferences, resulting norms for social interaction (e.g., open communication as a viable approach to conflict management in Western but not in Asian cultures) can negatively impact group dynamics. Overall, in order to be effective, intercultural group processes require high levels of awareness of structural influences and interpersonal differences.

Social Identity: In-Group and Out-Group Processes

The above-described phenomena refer to processes within organizational groups as opposed to processes between groups in organizations, an important issue to which we turn next. Social identity theory (SIT) is the most prominent psychological theory in this regard. Since this theory is rooted within psychology, it addresses individuals' social cognition with reference to group processes, as opposed to sociological theories, which cover entire collectives such as organizations. The following predictions derived from SIT are among the best demonstrated in social psychology. Individuals identify with the groups they belong to (i.e., the in-group) and derogate others who do not belong to their group. The resulting degree of identification with the in-group is at the cost of respect for and cooperation with individuals belonging to other groups (i.e., the out-groups). SIT emphasizes that all individuals are motivated to develop a positive social identity. The underlying processes are as follows: (1) Categorization; within their social environment, individuals categorize on the basis of who belongs to the in-group and who does not (in-group and out-group distinction). (2) Social comparison; individuals compare their in-group to out-groups, preferably in such a way that the dimension on which the comparison is performed produces positive distinctiveness (i.e., a feeling of positive uniqueness). If the in-group compares badly on a given dimension (e.g., group performance), it is argued that other dimensions are more important (e.g., to have a strong moral character rather than success), thereby protecting the positive distinctiveness of the in-group. Tajfel (1978) showed that even a minimal group context through a more or less arbitrary distinction between two groups (e.g., admirers of Vasily Kandinsky vs admirers of Paul Klee), suffices to produce in-group favoritism and out-group discrimination. Individuals from the

out-group as compared to in-group members are discriminated against more – for example, concerning the evaluation of positive attributes, interpersonal liking, and distribution of material rewards.

These processes are highly relevant in organizational contexts because subgroups within organizations predominantly think in terms of in-groups and out-groups – instead of perceiving the overall organization as their in-group. Therefore, organizational strategy is challenged. On the one hand, increasing in-group perceptions fosters a sense of togetherness, which in turn promotes engagement. On the other hand, overly strong in-group perceptions will hinder contact and cooperation between departments. Effective responses to these challenges following SIT encompass (1) communicating a common goal, which can only be achieved by joint action and cooperation of all groups in the organization; (2) providing members of each group with background information about tasks of the other groups; (3) rotating positions between groups; and (4) encouraging informal activities and personal relationships between members of different groups. Thereby, group borders remain permeable, and groups are open to each other's influence.

Groups and Organizational Change

Organizational change takes place frequently, often in terms of mergers and acquisitions or restructuring and downsizing of organizations. Leadership and group processes play a central role for the outcomes of organizational change (Peus et al., 2009) because change processes challenge existing structures on levels of individuals, groups, and the entire organization, and create a sense of uncertainty.

Steps of Organizational Transformation

In order to achieve the desired outcomes of organizational change, despite counteracting forces as described above, a number of basic principles and steps apply, which take into account psychological findings about the acceptance of change processes (Kotter, 1995):

- Creating a sense of urgency and inevitability of the change process
- Forming a group of powerful leaders who guide organizational members through the change process and act as positive role models
- Creating a clear vision and strategies to achieve the vision (i.e., giving direction and meaning to the change process)
- Communicating the vision through leaders and other channels in the organization (e.g., websites, newsletters)
- Empowering organizational members to actively engage in the change process, and giving them a voice in important decisions
- Creating short-term wins through visible improvements, and rewarding organizational members for their contributions
- Consolidating initial changes, and proceeding in further efforts
- Institutionalizing the new approach

Clarity, predictability, and procedural fairness play major roles in successful organizational change initiatives. Yet, in many cases, those who are responsible for the initiation and implementation of change do not reflect upon and adhere to these principles. Consequently, the success of many organizational change processes is put at risk due to the neglect of processes within and between organizational groups. Underlying is lack of consideration with regard to (1) organizational groups and their members' fears, hopes, and expectations in change processes; and (2) transparent communication about the whys and hows of organizational change. Taking the above-listed steps into account will foster successful change processes in organizations.

Change Through Non-Western Group Processes

Today's organizations are confronted with national as well as international competitors. In the car industry, for example, leading manufacturers like Toyota, General Motors, or Volkswagen are required to adapt production and distribution of nationally generated models to international markets in order to ensure their profitability. Thereby, a non-Western perspective to group processes has evolved, and a deeper understanding of such processes is desirable. One prominent example, the approach of lean manufacturing as introduced in the Toyota Production System, has influenced change processes in organizations worldwide. Lean manufacturing focuses on the fastest and most efficient way of producing and delivering high-quality goods to customers by eliminating all influences on the production that do not provide added value to reach these goals. The Toyota Production System specifically builds on the two concepts of just-in-time (i.e., continuous flow of production in which each step produces only what is needed in the next step) and *jidoka* (i.e., immediate stop to production when problems occur to prevent defective products). Similarly, the Japanese *kaizen* philosophy has been applied to business purposes with the aim of continuously improving organizational processes and standards by eliminating all redundant and unnecessary waste from the system (Spear and Bowen, 1999). Research and practice suggest that these principles contribute to organizational productivity. Further, it is important to consider how to best transfer these approaches from one culture into another. Management support, organizational communications, and enhanced learning opportunities are main pillars of successful implementation.

Group Processes and Leadership

The relevance of leadership for group processes in organizations has been widely acknowledged. We refer to theory and research in the areas of leadership in multinational corporations and shared leadership in groups because they represent important recent trends in literature.

Leadership in Multinational Corporations

The rise of multinational corporations is a result of increasingly globalized markets. Notwithstanding the advantages of

globalization, leading these kinds of organizations is particularly challenging to the extent that leadership takes places across and within national boundaries – including different cultural values and interpretations of effective leadership. As shown in the comprehensive Global Leadership and Organizational Behavior Effectiveness(GLOBE) studies, cultural values in part relate to culture-specific prototypes of leadership. Six second-order factors were empirically extracted: (1) charismatic/value-based, (2) team-oriented, (3) humane, (4) participative, (5) autonomous, and (6) self-protective leadership. While charismatic/value-based and team-oriented leadership were endorsed as part of effective leadership across cultures, humane and participative leadership were not fully universally endorsed, and perceptions of autonomous and self-protective leadership varied across cultures (Dorfman et al., 2004). Overall, leadership in multinational corporations is confronted with the challenge to integrate universally shared values (e.g., fairness, appreciation, motivation) with the specific value system of each individual culture. Promoting integration is a key contributor to the success of today's globalized organizations through effective leadership and group processes.

Shared Leadership in Groups

As an alternative to common, hierarchical approaches to leading individuals and organizations, pluralistic forms of leadership have gained increasing attention over the last two decades. Shared leadership is an example of pluralistic leadership that comprises an innovative integration of leadership and group processes, wherein group members lead each other toward goal achievement (Pearce and Conger, 2003). Many characterizations evolved, taking into account that shared leadership (1) relies on dynamic and interactive group processes integrated with top-down and bottom-up influence, (2) stretches along a continuum of few to many different sources of leadership in a group, and (3) comprehends shifting leadership roles over time in response to situational or contextual demands. The emergence of shared leadership – as opposed to hierarchical leader–follower relations – goes hand in hand with a change of perspectives on organizational structures (e.g., systems thinking, decentralization, and self-management in work groups). Research paradigms have been broadened such that the study of shared leadership is predominantly based on (1) ratings of entire teams with established leadership questionnaires extended to the group level; (2) ratings of the extent to which each individual team member shows certain leadership behaviors, and subsequent computation of group-level indices; and (3) empirical modeling of multilevel data. Hitherto empirical results from organizational contexts suggest that shared leadership positively influences desired outcomes, like team effectiveness, top management team performance, and group processes in virtual teams, exceeding the positive effects of hierarchical leadership. Yet, structural aspects of group functioning (e.g., group members' demographic and/or deep-level diversity) may hinder shared leadership. Therefore, further theory and research are needed to explore the premises to as well as advantages and disadvantages of leadership through group processes for organizational functioning in greater detail.

Conclusion and Perspectives

As the presented theoretical and empirical insights demonstrate, group processes are a typical example of the need for close interdisciplinary cooperation (e.g., between social psychologists and organizational psychologists) to fully capture the mechanisms of organizational functioning. Moreover, it was our goal to show the connections between social psychology, organizational psychology, and practice in organizations. Indeed, it appears that nothing is as practical as a good theory. Of course, no all-encompassing theory of group processes exists, but as we have shown, several small group theories are directly applicable to manifold organizational phenomena.

Future research should be devoted to (1) compare, integrate, and differentiate predictions based on existing group theories; (2) pursue new methodological pathways toward the study of group processes (e.g., longitudinal designs; measurement and analysis at individual, group, and organizational levels simultaneously; integration of social psychology and neuroscience); and (3) develop and evaluate evidence-based training and development programs for enhanced group functioning in organizations.

Group Processes in the Classroom

Angela M O'Donnell, Rutgers, The State University of New Jersey, New Brunswick, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Group processes in the classroom occur when peers engage in a common task and can include a variety of both social and cognitive processes. The focus of this article is on cooperative or collaborative groups of peers. Thus, group processes occur during peer learning. The article describes a number of theoretical orientations toward peer learning that suggest different explanatory mechanisms for effective peer learning. These orientations have different implications for important decisions in the classroom. The relationship between what researchers know about effective group processes and the use of this knowledge by teachers is examined. Two models for considering group processes are described which attempt to integrate the varying theoretical orientations to peer learning. These models may make it possible to provide a better linkage between empirical research and classroom practice. Finally, directions for future research are outlined.

Interest in group learning and group processes has a very long history and remains a key focus of current efforts to improve education. Group processes in the classroom occur when peers engage in a common task and can include a variety of both social and cognitive processes. Cooperative and collaborative learning in the classroom has been associated with a variety of positive and social outcomes. Cooperative learning has been shown to be more effective than individualistic learning or competitive learning (Johnson and Johnson, 1989; Slavin, 2012). Students who participate in cooperative learning activities develop more positive relationships with peers including academically handicapped peers and have more positive attitudes toward subject matter (Johnson and Johnson, 1989). Furthermore, the social standing of students with learning disabilities (Fuchs et al., 2002) improves as a result of participating in peer learning activities.

There is no single method for arranging group interactions in the classroom. The focus of this article is on cooperative and collaborative groups of peers and the various theoretical approaches that attempt to explain group processes in these kinds of groups. These approaches propose varying mechanisms for the effectiveness of group learning. For example, some approaches emphasize within-group cooperation and between-group competition that result in the attainment of rewards. Other approaches do not rely on the provision of external rewards. Determining which method of fostering group interaction is most effective for producing academic achievement or positive social outcomes is complicated. Comparisons of empirical findings across studies conducted from different theoretical perspectives are very difficult because of the wide variation in tasks used, duration of studies, roles of teacher and students, outcome measures, and other variables such as group composition, group size, or the use of individual accountability. One consequence of the variation in theoretical approaches is the fact that these approaches require different decisions with regard to key variables such as group size or composition and the use of rewards. Group processes can be best understood within particular theoretical approaches. This article will not address the influences of specific variables but will instead focus on the delineation of the various theoretical perspectives and the linkage to practice.

Theoretical Approaches to Group Processes

Different theoretical approaches to peer learning propose different underlying mechanisms or processes that come into play when a group works together (O'Donnell and O'Kelly, 1994). Slavin (1996) described two main classes of orientation toward peer learning: a social-behavioral orientation that includes motivational and social cohesion approaches, and a cognitive orientation that includes elaboration and developmental theories.

Social-Behavioral Perspective

The concept of interdependence among group members is fundamental to the motivational and social cohesion perspectives on cooperative learning, although they differ in how interdependence is created and sustained. When group members are positively interdependent, the success of one member can occur only if other members are also successful. An example of a positively interdependent group is a tug-of-war team. In contrast, negative interdependence occurs in competitive situations in which one person's success requires that another person fail. An example of a negatively interdependent event is a track race. Only one person can win which means others must fail to meet their goals.

In the social motivational approach, interdependence is created by the use of group rewards. The principle underlying the use of rewards is that students will be motivated to help their peers to gain rewards. In Student Teams Achievement Divisions (Slavin, 1995), students work in small groups to master material that the teacher has presented using the teacher's preferred teaching method. Each student takes an individual quiz on the material, and points are assigned to the group based on each individual's improvement score. The improvement score is calculated based on the student's prior performance. Students are accountable for improving their achievement over past performance. Team points are awarded based on levels of improvement. The advantage of using improvement points is that learners of varying abilities can contribute equally to the total group score. High achieving students are less likely to feel resentful in working with less

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92078-6

capable students who in turn will be less likely to feel negative peer pressure. Group rewards are assigned based on the team's number of points. A key component of this approach is the reliance on individual accountability. Evidence of the effectiveness of this approach comes from a large number of studies (Slavin, 1996, 2012). The kind of learning task used in this approach, however, tends to focus on basic skills or factual knowledge and it is unclear whether this approach is effective in promoting higher-order skills. Students quiz one another using fact sheets that include the answers on the back of the sheet. The cognitive processes addressed are ones of rehearsal and some elaboration.

Social Cohesion Perspective

In the social cohesion approach, interdependence derives from a motive of care and concern experienced by group members for one another (Johnson and Johnson, 1994). Group members help one another because they are concerned about their peers. Teaching social skills that will support this kind of interdependence is an important emphasis in a social cohesion approach. Depending on their prior experiences, students may be unskilled at productive interaction. Classroom teachers need to spend time to encourage positive social norms, modeling helping behavior, and providing feedback on students' social interactions.

The Johnson's Learning Together technique (Johnson and Johnson, 1994) illustrates the social cohesion approach. The empirical evidence supporting this orientation toward collaborative learning as a method for enhancing academic achievement is much weaker than that supporting the motivational perspective. Slavin (1996) notes that cooperative learning methods that emphasize team building and group process, but do not provide group rewards, are not effective but when they are combined with the use of rewards or require accountability, student achievement from group learning exceeds individualistic learning. Slavin concluded that individual accountability and group rewards are critical to the success of cooperative learning methods.

Not everyone subscribes to the idea that rewards are necessary to create cohesion or interdependence. Cohen (1994) believes that cooperative learning that uses group rewards may be useful for lower-level skills but may not either be necessary or helpful for promoting higher-order skills. Thus, decisions about whether to adopt a motivational or social cohesion approach to peer learning may depend on the desired outcomes from group interaction.

Cohen (1994) emphasizes a different source of social cohesion, suggesting that the interest value of the task in which students engage will create the kind of interdependence necessary for students to succeed. Such tasks are likely to be authentic and engaging. Social cohesion is promoted by reducing the influence of status differences on students' interactions. When a student has high status in a group, he or she participates more, provides explanations, asks questions, and is generally active in group work (Cohen, 1982). A student with low status often does not have access to the materials being used by the group, participates less, and is often in the position of help-seeker rather than an active participant in the group. When tasks are used that are interesting to students and when positive social and cognitive interaction is supported, difficulties associated with status differences among students are ameliorated. When students have low status in a group, they participate less and in ways that do not promote achievement (Cohen, 1982). Explicit rewards in this context may only exacerbate the problems created by differential status in the group. Cohen and her colleagues have successfully promoted social cohesion in groups by reducing status differences among group members so that they are oriented to accept that all students *can* contribute to task accomplishment. Complex and interesting tasks are necessary for this level of inclusion to occur (Lotan, 2003). Cohen and her colleagues have been very successful in promoting student achievement using Complex Instruction (Cohen, 1994; Cohen and Lotan, 1995). Results from studies by Cohen and her colleagues suggest that the nature of the task may have important implications for the kind of accountability that is needed to promote effective group learning by improving group processes within the classroom (Cohen, 1994).

Cognitive/Elaboration Perspectives

The third perspective identified by Slavin is a cognitive/elaboration approach and is based on information processing theory. The role of group interaction from this perspective is to increase an individual's active processing of information by providing opportunities for restructuring and elaborating knowledge. The function of the group is to provide an individual with a mirror to his/her own cognition. Group learning techniques influenced by this perspective tend to provide some structure to the interaction of students by emphasizing the cognitive processes in which students must engage. Examples of work influenced by this perspective include the use of scripted cooperation by O'Donnell, Dansereau, and colleagues (O'Donnell and Dansereau, 1992), reciprocal peer questioning (King, 1999), reciprocal teaching (Palinscar and Brown, 1984), and the work of Noreen Webb (1992). The empirical evidence supporting the use of these techniques is strong.

The quality of discourse in group interaction is critical from this perspective and will have an influence on the outcomes from group interaction. Webb (1992) and Webb and Palinscar (1996) have shown that the quality of explanations that are provided in a group is linked to achievement. Giving explanations is more strongly associated with achievement than receiving explanations. King (1999) has also shown that instructional efforts to improve the quality of discourse by teaching students to ask questions that facilitate knowledge construction is very effective.

Developmental Perspectives

A fourth approach to understanding cooperative or collaborative groups relies on two different theories of development. From a Piagetian perspective (De Lisi and Golbeck, 1999), peers can learn from one another because they can provide opportunities for cognitive conflict and conflict resolution. Groups that experience mutuality of influence and power are most likely to provide a context within which cognitive development can occur because they are more likely to include

differences of viewpoint. Children who have not attained the principle of conservation often develop and maintain conservation concepts when they have worked with a child who has already developed this concept (De Lisi and Golbeck, 1999). Much of the work on conceptual change teaching in science education has been influenced by this perspective (e.g., Sinatra and Pintrich, 2003; Southerland and Sinatra, 2003).

From a Vygotskian perspective (Hogan and Tudge, 1999), children acquire knowledge and skills that are first modeled in the community and are subsequently internalized by the individual. When cooperative learning is anchored in Vygotskian theory, it is concerned with the larger community of practice in which individual learning is accomplished. Key processes include the scaffolding of the learner's performance by a more expert individual. The difference between what an individual can accomplish alone and with the assistance of a more knowledgeable adult or more capable peer is defined as the zone of proximal development.

Sociocultural and Combined Theoretical Perspectives

A fifth perspective that undergirds such group learning techniques such as Communities of Learners (Brown and Campione, 1990) may be identified. It includes the developmental perspective of Vygotsky, with its emphasis on the sociocultural basis of learning, and a social cohesion approach in which such learning is motivated by care and concern. Other forms of cooperative learning borrow from multiple perspectives in making choices about the selection of tasks and the organization of learning (Van Meter and Stevens, 2000).

The importance of the varied perspectives on collaborative and cooperative learning can be understood from the perspective of a classroom teacher who must make a variety of decisions about how to organize group learning in the classroom and what kinds of processes he or she wishes to promote. Table 1 delineates key differences among those perspectives as they relate to instructional decisions, problems that may arise from such decisions, and strategies for averting such problems. The goal is to promote positive group processes (e.g., helping) while minimizing negative group processes (e.g., evaluation of persons). Table 2 illustrates how four of these perspectives conceptualize the mechanisms that underlie effective cooperative and collaborative learning.

Table 2 Mechanisms for promoting learning from a variety of theoretical perspectives

Theoretical perspective	*Mechanism for promoting learning*
Social motivational	Interdependence created through motivation
Social cohesion	Interdependence created through care and concern
Cognitive elaboration	Deeper processing of information
Cognitive development–Piaget	Adaptation as a result of cognitive conflict
Cognitive development–Vygotsky	Modeled behavior that is scaffolded and internalized

Influences on Group Processes in the Classroom

A number of factors related to classroom practices influence group processes in the classroom. Three key dimensions of classroom practices are (1) the quality of students' discourse, (2) the role of the teacher in the collaborative classroom, and (3) the tasks selected.

Quality of Discourse among Participants

Simply being in a group does not necessarily mean that students will derive academic or social benefits from the group interaction. Negative processes can also occur in a group. An example of such a process is that of social loafing

Table 1

	Theoretical perspectives				
	Social-behavioral		*Cognitive*		
				Developmental	
Considerations	*Motivation*	*Social cohesion*	*Elaboration*	*Piagetian*	*Vygotskian*
Goals/incentives	Rewards essential	Rewards nonessential	Rewards nonessential	Rewards nonessential	Rewards nonessential
Group size	Large (4–6)	Large (4–6)	Small (2–4)	Small	Dyads
Group composition	Heterogeneous	Heterogeneous	Heterogeneous	Homogeneous	Heterogeneous
Tasks	Rehearsal	Rehearsal/integrative	Rehearsal/integrative	Exploratory	Skills
Teacher role	Director	Facilitator	Facilitator	Facilitator	Model/guide
Potential problems	Use of reward	Social loafing Cognitive loafing	Unequal participation	Inactive No cognitive conflict	Poor help-giving
Averting problems	Improvement scores	Team building	Direct instruction in help-giving	Structuring controversy	Providing adequate time/dialogue
	Simpler tasks	Conflict resolution strategies	Model help-giving		Direct instruction in help-giving
	Social cohesion	Discuss group processes	Scripted interaction		Modeling help-giving

(Latané et al., 1979) in which an individual or individuals reduce their efforts in a group in comparison to how they would have performed if not in a group. The kinds of tasks on which students work will influence the quality of discourse within a group. The quality and depth of the discourse among students significantly affects the outcomes from group interaction (Webb and Farivar, 1999).

Task instructions can also influence the quality of discourse within a group. In one study by Chinn et al. (2000), pairs of students worked together to generate and evaluate conclusions from experiments they conducted with electrical circuits. Half of the pairs were asked to decide if each of three conclusions were 'okay' or 'not okay.' The other half of the students were asked to examine the same set of three conclusions and determine which of the conclusions was the best conclusion. Results of the study showed that the level of argumentation was much richer among pairs of students who were asked to choose the best conclusion.

Even when high achieving students work together, outcomes from collaborative learning depend on the quality of interaction (Barron, 2003). Barron examined the interaction of 12 triads of 6th graders engaged in problem-solving. Features of the dialogue between group members were predictive of problem-solving outcomes. When correct ideas were proposed and accepted, group outcomes improved. Less successful groups ignored or rejected correct ideas or did not link new ideas to previous ideas. Prior achievement was not predictive of successful outcomes.

The heterogeneity of intellectual ability and social skills within the group will also influence the quality of discourse within a group. Students who vary in gender, race, ethnicity, and ability or who experience special needs contribute to heterogeneity in the classroom. The variables may also have an influence on the effectiveness of the group. These differences can enhance learning as students with different experiences and background may deepen the quality of discourse by the introduction of varied perspectives and/or by the use of questions.

If one adopts a Vygotskian view of peer learning, intellectual skills must be modeled before a child can internalize them. The advantage of having a heterogeneous group is that there is an increased likelihood that someone in the group will be able to model higher-level thinking skills and may also be able to scaffold the efforts of less skilled individuals. Most students need support in generating the quality of discourse that is associated with learning. Teachers can promote high levels of cognitive activity by asking questions that vary in complexity (King, 1991; King et al., 1998).

The Role of the Teacher

Teachers' roles are key components of effective peer learning. These roles can be very complex and include such varied roles as those of community builder, preparing of learning activities, model of problem solving and other intellectual skills, coordinator of activities, and evaluator of students' work. All of these roles contribute to the promotion of effective group processes. Different peer learning activities require different stances with respect to students, tasks, and outcomes. Teachers must take into account both the social context in which learning occurs and the cognitive processes that are either supported or hindered in that context. They need to analyze their classrooms to determine whether there may be obstacles that limit the cognitive opportunities available to students or prevent them from making use of those opportunities. Teachers can adopt many roles in relation to the use of peer learning.

The quality of discourse from students is not the only discourse that is important. The example provided by the teacher in terms of discourse is also important. Webb et al. (2006) found that students reproduce the discourse of teachers in the context of a semester-long program of cooperative learning in middle school mathematics classes. They concluded that the models of discourse presented by the teacher were imitated by students. When the teacher modeled low levels of cognitive activity, the students followed suit. Teachers experienced difficulty in changing their behaviors to ones in which they allowed students authority for discourse. It requires a lot of professional development for teachers to effectively use group processes in the classroom.

When more than one person is engaged in a learning task, social processes are involved. In using cooperative groups or other forms of peer learning, the teacher also needs to provide feedback on students' interactions. They may provide direct instruction in the use of appropriate social skills or strategies for disagreeing with peers without being disrespectful. Cohen and colleagues have shown that when students are given criteria for an acceptable group product and use those to evaluate their work, their interactions improve and their learning increases (Cohen et al., 2002).

The Role of the Task

Teachers need to set goals for any task they assign to groups of students. Teachers may select tasks with the goal of motivating or engaging students, providing a context for social interaction with a student who is having particular difficulties, getting students to learn factual material, or getting them to engage in higher-order reasoning and thinking skills. Depending on the goals of the task, the kind of peer learning employed will vary.

Classroom tasks can be classified along a number of dimensions. The first dimension is complexity. Tasks will vary in the demands they make on students' cognitive, affective, social, and metacognitive processes. Complex tasks work best in conditions where reward contingencies are not high. Simple tasks may fail to interest students who may respond by engaging in social or cognitive loafing. Tasks can be simple and require simple cognitive strategies, such as rehearsal. An example of a simple task is that of memorizing the names of the capitals of states which requires rehearsal. Tasks require different kinds of knowledge. Those that involve basic knowledge acquisition are those in which information is encoded into the student's memory for later recall. Strategies for helping students master such tasks include teaching them memorization and rehearsal strategies, such as the use of mnemonics, summarization, and elaboration strategies.

Other tasks require more complex cognitive skills. An example of a complex task is asking students in small groups to design a zoo. To perform this task, students need to do research on the kinds of areas that are included in a zoo, learn about the kinds of animals that might inhabit the zoo, and learn about how to care for the animals. Tasks like these require

students to pose their own questions, explore alternatives, gather information, organize the information, generate evidence or arguments in support of ideas, and draw conclusions. The techniques that support basic knowledge acquisition and rehearsal are not sufficient to promote these kinds of higher-order thinking. Tasks that are more open-ended or require more collaborative knowledge construction call for cooperative techniques that are less structured in order to permit the kinds of interactions that promote the cognitive complex that will result in the desired outcomes.

A second dimension along which tasks vary is the degree to which group interaction can promote positive learning outcomes. Cohen (1994) distinguished between individual and group tasks. This distinction differentiates between tasks that are better done alone and those that will be best performed by a group. According to Cohen, a group task is one that "requires resources (information, knowledge, heuristic problem-solving strategies, materials, and skills) that no single individual possesses so that no single individual is likely to solve the problems or accomplish the task objectives without at least some input from others" (1994, p. 8). Such tasks are open-ended or less structured and require problem solving. Students can approach complex tasks from a number of vantage points and have multiple opportunities to demonstrate and further develop their intellectual competence. These tasks which are concerned with important content require positive interdependence among group members and the individual accountability of all members. Such tasks also include clear criteria for how the group's product will be evaluated (Lotan, 2003). Lotan (2003) refers to these kinds of tasks as group-worthy tasks. Deploying these kinds of tasks to promote learning requires a great deal of time and expertise on the part of the teacher.

There are some risks associated with open-ended tasks. Students may be drawn into negative social interactions; some may be easily frustrated if the task is ambiguous; and some will not participate fully. A combination of high risk of failure and task ambiguity may result in excessive demands on students' social and affective skills resulting in impairments in the use of cognitive or metacognitive strategies. Various strategies, such as the social skills training advocated by the Johnsons, the status interventions proposed by Cohen, and close monitoring of groups, can limit these negative outcomes.

It is important to note that not all students will be ready to assume complex roles and strategies. Depending on their history of working in groups, students may not be sufficiently independent to work effectively in groups. Students who have not worked in cooperative groups will need training and gradual experience in taking more responsibility for their learning. Likewise, students who have not valued educational achievement in the past will not suddenly become passionate about learning without a major effort to change their values regarding achievement. In such circumstances, a teacher will need to work to establish a culture of valuing academic achievement.

Research and Practice

Despite the burgeoning research findings that might assist teachers in making choices about grouping for instructional purposes, teachers do not seem to rely on the empirical research for guidance when making such choices (Antil et al., 1998). However, few studies have examined teachers' beliefs about group processes in the classroom.

Teachers' Use of Cooperative Learning

The research findings from any of the perspectives described seem to have little systematic influence on teachers' choices about groups. Although Slavin (1996) is convinced that empirical evidence supports the use of group rewards, he noted that there was quite a reluctance on the part of classroom teachers to use them.

Antil et al. (1998) conducted a study of elementary school teachers' conceptualization and utilization of cooperative learning. Eighty-five teachers responded to an initial survey. Ninety-three percent of the respondents reported that they used cooperative learning for both academic and social reasons. In interviews with 21 of these teachers, Antil et al. found that the majority of the teachers structured tasks to create positive interdependence and taught students skills for working in groups. Few, however, employed recognized forms of cooperative learning and, in particular, did not link individual accountability to group goals. No data were presented, however, that linked classroom practices related to cooperative learning to student achievement. It is clear from this study that teachers do not implement the particular practices of cooperative learning that research has shown to be effective. However, when teachers receive extensive professional development, the effects on student achievement can be powerful (Schlutz, 2000).

Another interesting feature of teacher behavior with respect to collaborative learning is the quality of discourse modeled by the teacher. Webb et al. (2006) have shown that the quality of discourse by students in groups parallels that of the teacher. When teachers modeled low-level discourse such as recitations or assumed the responsibility for problem solving, students tended to follow suit and confine their contributions to lower-level cognitive activities such as providing terminal answers or asking for simple levels of help.

Usable Models of Group Process

The availability of multiple perspectives on peer learning and the proliferation of specific techniques may contribute to the disconnection between the available research findings and their use by classroom teachers. The kind of classification system represented in **Table 1** is rarely presented to either preservice or in-service teachers. Usable models of per learning that can guide practical decisions are needed. Such models need to clearly link expected outcomes to classroom processes and teachers' actions or decisions.

Slavin (1996) proposed a model of effective peer learning with motivation at its core. Motivation is necessary in order for students to engage in the active processing (e.g., explanations) that is linked to achievement. The keys to motivating students, according to Slavin, are group rewards and individual accountability. Teachers can act to create and sustain children's motivation that will allow them to link will and skill in pursuit of academic achievement.

Van Meter and Stevens (2000) emphasize the quality of discourse within the group as the key variable in effective group learning. Other instructional choices should be such that the quality of discourse is enhanced. Thus, task instructions and group composition are only interesting insofar as they influence the quality of discourse among peers.

These two models provide a simple set of goals for teachers using group learning. Coherence among classroom decisions about fundamental aspects of arranging instruction (e.g., group size, group composition, and type of task) is more likely to occur if there is a clear goal in place (e.g., motivate students to engage in active learning). Teachers in the Antil et al. (1998) study reported that they did not subscribe to particular cooperative techniques because they wanted to maintain their decision-making autonomy. The two models that are briefly described here with their emphases on motivation and discourse provide a set of superordinate goals that can accommodate teachers' need for autonomy, while preserving a principled approach to decision making about group processes.

Future Directions

Given that teachers seem reluctant to use group rewards (Slavin, 1996), it is important to specify the conditions under which alternative methods of creating interdependence among group members can be effective. What are the kinds of tasks for which extrinsic rewards are not necessary? Answers to this question lie in the analysis of the kind of processes in which students engage when they are involved in interesting and challenging tasks. A clearer understanding of effective processing of complex tasks may make it possible to find alternatives to rewards.

The tension between theories of group processes and classroom practices of group learning presents the richest source of future research questions. Teachers' beliefs about learning lie at the fulcrum of their abilities to implement effective group learning in the classroom. The relationships between teacher beliefs, implement practices, and student achievement remain untouched as research questions. Research on this set of relationships would provide valuable insights that could inform teacher preparation and in-service professional development and also improve classroom practice of group learning.

Abstract

Groups lie at the core of the human experience. Group processes encompass such a wide range of phenomena that the social psychological study of group processes has many different focuses. The study of group processes, in general, concerns the cognitive and social causes and consequences of human aggregation. This article provides a history and review of group processes research including information on group formation, group performance, and group decision making; of how people are socialized into groups and roles within groups; and of how groups influence their members through persuasion, leadership, and norms.

What Is a Group?

Groups occupy much of our day-to-day life and have a profound effect on our actions, thoughts, and feelings. People work in groups, socialize in groups, and play in groups. Furthermore, people represent their views and attitudes through groups. The variety of groups we may belong to and identify with is vast – it includes groups based on ethnicity, ability, gender, nationality, religion, political ideology, profession, hobbies, and so on. Groups can be described in various ways emphasizing specific characteristics such as mutual dependence, cohesion, communication, entitativity, influence, structure, and shared identity. The tendency to join with others in a group is one of the most fundamental characteristics of humans, and the processes that unfold within groups leave a lasting imprint on both their members as well as society.

Numerous definitions of groups have been proposed in the literature. There is, however, little consensus on a single social psychological definition of a group. The dominant view characterizes a group in two ways. First, a group consists of a collection of individuals who interact with one another. Second, in all groups there are processes that are interpersonal processes among a number of people. Alternative perspectives contend that groups possess 'emergent properties' that arise from interactions among members and therefore are qualitatively distinct from members' individual characteristics.

Early observers of group behavior (including Durkheim, McDougall, and Mead), more contemporary theorists (including Sherif and Tajfel), and those who espouse the social identity and intergroup approach to studying groups argue that the analysis of groups in terms only of interpersonal processes is reductionist – it does not adequately address questions to do with group processes, but instead deals only with interpersonal processes among more than two people. Although, the issue of 'what is a group' continues to be unresolved, there have been more recent attempts to integrate small group perspectives, intergroup perspectives, and cognitive perspectives.

Studying Group Processes

Interest in, and study of, group processes has ebbed and flowed. The 1930s marked the beginning of systematic research on group dynamics by social psychologists. Prior to World War II a number of classic studies were conducted including Sherif's experiments on the development of social norms under uncertainty. The late 1940s and early 1950s marked the golden age of groups research, a time when it gathered momentum and helped set experimental social psychology off on its current expansion. It was during this time, after World War II, that researchers began to investigate issues of leadership and conformity, as possible avenues for understanding how and why human atrocities associated with the Holocaust could occur.

Group processes research thrived until about the mid-1960s when it suffered a fairly rapid decline in popularity due to an increased interest in individual-level phenomena, attribution theory, and social cognition. Groups research went through a relatively quiet period until the early 1980s when it started to show strong signs of recovery, mainly attributed to increased interest in cognitive perspectives and European approaches to studying groups (i.e., social identity and minority/majority influence). There have been a number of explanations offered for the apparent demise of traditional groups research such as the financial and time constraints of conducting research on interactive groups and the fact that data from group research are rarely neat, tidy, and easy to explain (Levine and Moreland, 2012).

Group Formation

Why do people join and identify with groups, and why do they prefer some groups over others? The answer to these questions depends on a number of factors such as how the group is defined, how people come to join the group, and the degree of free choice in the decision. However, there are a number of circumstances, goals, and motives that tend to lead people to form, join, and remain in groups.

People are more likely to associate and form groups with certain people such as those who are in close proximity, those who express similar attitudes and values, and those who respond positively to them. Groups exist for a reason; they make it easier to attain goals that cannot be attained alone. In groups, people can coordinate their actions and cooperate to achieve goals that they could not attain on their own.

Motivations associated with group affiliation are basic and central to our existence. People have a basic need to belong and this causes them to affiliate with others. According to this perspective, self-esteem is seen as a meter of successful inclusion and group belonging. A sense of belonging produces a sense of self-esteem and self-worth. Some social psychologists believe this perspective to be too simplistic and argue that it does not account for membership in large-scale social categories or for the identity functions of groups. An alternative theory, terror management theory (Greenberg et al., 1997), posits that fear of one's own death is the main motivating force that leads people to join groups. Group affiliation provides people with symbolic immortality through social validation of their cultural worldviews that outlive them, and thus reduces existential anxiety and raises self-esteem. A third perspective, uncertainty–identity theory, proposes that the main motivation responsible for belonging and identifying with groups has less to do with self-esteem and anxiety reduction and more to do with individuals' desire to reduce uncertainty about themselves, their attributes, and their place in the world (Hogg, 2012).

Group Development, Cohesion, and Commitment

Groups are dynamic structures – new members join, old members leave, members are socialized into the group, and the group in turn is imprinted with the contribution of individuals. Most theorists propose that small groups go through five stages of development: orientation (forming), conflict (storming), structure (norming), work (performing), and dissolution (adjourning). Cohesion, in most cases, is a consequence of a period of group development. It is a term used to characterize the psychological process that transforms an aggregate of unrelated individuals into a group. Cohesion, a group-level construct, is one of the most theoretically important concepts in the study of group processes. Cohesiveness refers to the overall solidarity of the group – the property of a group that affectively binds people, as group members, to one another and to the group as a whole giving them a sense of oneness.

For many years, cohesion was studied in terms of interpersonal attraction. This individualistic conception of groups emphasizes individuals' attachment to individual other group members and overlooks their feelings about and attachment to the group as a whole. Subsequently, however, cohesion has been studied from a social identity perspective. From this viewpoint, cohesion is a consequence of the cognitive process of identifying with the group (i.e., self-categorization in terms of the group's defining features) and feelings about other group members are determined by how well those members match the group's prototype. A group is cohesive when its members are committed to the group and regard one another as good/prototypical exemplars of the group.

Group Influence

Groups influence the thoughts, feelings, and behavior of their members in many different ways.

Direct Influence and Persuasion

Groups tend to be aggregations of like-minded people and so those group members who do not go along with the majority of the group are subject to direct influence attempts. Groups use direct influence to try and persuade members to come into line with the group. Persuasion attempts may range from relatively polite requests all the way up to direct orders reinforced by threat and potential force. Persuasion is generally more effective if the source of influence has a degree of legitimate power or authority within the group (e.g., expert source or leader; Hogg, 2010). Direct influence attempts usually produce compliance, a superficial, public yielding to influence, which is not accompanied by underlying cognitive or attitudinal change. Individuals go along with the group for instrumental reasons which may include a desire to obtain a reward (i.e., social approval) or to avoid punishment.

Indirect Influence and Group Norms

Groups are powerful agents that can also influence members indirectly through group norms – shared beliefs about what is appropriate conduct for a group member. Norms mark group boundaries and describe and prescribe how group members should behave. Groups conform to norms in the absence of direct social pressure. Research on conformity suggests that there are three main processes of social influence: 'normative influence,' 'informational influence,' and 'referent informational influence.'

Normative influence is an influence to conform to the positive expectations of others. People comply with the norms of the group for instrumental reasons such as to gain social approval and acceptance, avoid disapproval, or achieve specific goals. Normative influence is only effective when people believe they are under surveillance by the group; therefore this form of influence creates surface-level, situation-specific compliance rather than underlying cognitive change.

Informational influence refers to an influence to accept information from others as evidence of reality. Individuals desire to feel that their perceptions, feelings, and beliefs are correct and appropriate in a given situation. When people feel uncertain about how they should think or behave (e.g., because of ambiguous stimuli or social disagreement) they initially make objective tests against reality. But if this is not possible, they will make social comparisons to gauge the correctness of their behavior (Festinger, 1954). Effective informational influence causes true cognitive change which may lead to behavioral change.

Social identity theory (Turner et al., 1987) argues that normative influence and informational influence represent a dual-process perspective that has focused on interpersonal dependency and underemphasized the role of group norms and group belongingness. This perspective proposed a third form of social influence associated with identification-based conformity, referent informational influence. There are three stages in which conformity to the group norm evolves: (1) individuals identify as a group member, (2) a contextually-appropriate norm (or prototype) is constructed or identified, and (3) group members internalize the norm, assimilate themselves to the norm, and use it as a guide for their own group behavior.

Group Structure

Interactions among group members are rarely random. Instead, they tend to follow regular patterns that reflect the underlying structure of the group. Group structure reflected in the roles, status relations, and communication networks, define and organize the group, and shape group processes.

Positions, Roles, and Status

Not everyone in a group performs the same function. They have differing *positions*, and people perform different tasks that they are expected to accomplish for the group. That is, people or subgroups of people occupy roles. Roles are coherent sets of behaviors that people occupying specific positions within a group are expected to perform. Some roles are assigned and others are acquired over time. Regardless of how people come to occupy roles, they emerge to help the group function as an integrated entity and to facilitate goal attainment. Levine and Moreland (1994) developed the 'group socialization model' which describes the ways roles are allocated to individuals and the ways in which members move in and out of roles within a group as a function of their commitment to the group.

In theory, roles could be defined simply in terms of task and need not imply differences in status; however roles are rarely equal – some are more desirable than other, and thus have more power and status attached to them. Social psychologists suggest that with increasing role differentiation also comes greater differentiation in status for those roles and thus hierarchy. It is the group members' expectations that lead to this status differentiation. Status tends to be given to those group members who have specific status characteristics (skills and abilities directly related to the group's function) and/or diffuse status characteristics (general qualities that are thought be indicators of competence). Groups do not always allocate status fairly. Group members let general status (i.e., diffuse status) characteristics influence their expectations; leading individuals who have achieved or been ascribed authority or prestige in one context enjoy a higher status in other, unrelated contexts.

Communication Structures

Another feature of group structure is the patterning of information exchange and ways in which group members communicate with each other. Communication structures tend to become more complex and varied as groups increase in size. Centralized communication structures channel all communication through a single, central communication hub (often a leader), while decentralized communication structures allow freer communication among all members because no one position is more central than another. For relatively simple tasks, centralized structures improve group performance; the hub person can receive, process, and disseminate information effectively and efficiently allowing other group members to focus on their roles. For tasks that are more complex and require greater information exchange and processing, decentralized structures are superior. This type of communication structure prevents any one member from being overloaded and overwhelmed with complex information, and thus improves overall group performance.

The nature of the communication structure also affects group functioning, overall commitment, and satisfaction with membership in the group. For example, because centralized networks have lower levels of closeness, the overall level of member satisfaction in such groups tends to be low. Communication networks can be traced and classified using an 'interaction process analysis' method, which documents the underlying recurring patterns of interpersonal behavior in a group. However, with the explosion of computer-mediated communication (CMC), methodologies for studying communication networks will have to adapt to changes in the nature of interaction between individuals.

Leadership

Groups normally require guidance and support as they strive to meet their goals, and the individual who coordinates and motivates the group can profoundly shape the group's future. This individual, the leader, occupies one of the most important and certainly the highest status role in the group. Leadership can be defined as a process of social influence through which an individual guides others in the attainment of a collective goal, often by mobilizing, directing, coordinating, supporting, and motivating their efforts (Hogg, 2010). There is much theory and research on leadership – particularly in the organizational and management sciences (Yukl, 2010). Some of this work focuses on the emergence and acceptance of leaders, but most of it focuses on their effectiveness. Effective leadership is often operationalized as being able to successfully define and set collective goals and influence others to achieve this vision for the group.

Effective leadership is thought to be a function of a match between leadership style or individual personality and the demands posed by the task or situational. These contingency theories of leadership recognize that the effectiveness of a particular leadership style is dependent on the properties of the leadership situation – some styles are better suited to some situations than are others.

Social cognitive theories of leadership suggest that leaders are more favorably appraised and thus more effective if followers perceive them as closely matching general or task-specific leadership stereotypes. However, when a particular social group becomes salient and is important to member's self-concept, leadership may be viewed as an identity process in which group prototypicality becomes important. Under these circumstances group prototypical leaders are more favorably evaluated, more strongly supported, and thus more effective.

It is because leadership is a role that leadership dynamics also involve followers – followers must follow in order for leaders to lead. Transactional leadership perspectives emphasize the dynamic nature of leader–follower interaction, an interaction in which leaders and followers provide mutual support and gratification. Generally, followers tend to endorse leaders who have good leadership qualities, who have the abilities to benefit and promote the group as a whole, and who are good group members or have been good group members in the past. Transformational leadership theories view group transformation as the key function of leadership and focus on the charismatic properties or behavior of leaders that allow them transform groups.

Deviance

Most groups are structured in terms of the central or marginal group membership of specific members. Those members that embody the group's attributes often have influence over the group and occupy leadership roles whereas those who significantly deviate from the majority are often treated as 'black sheep.' There are a number of variables that affect how groups respond to deviants such as the extremity and content of the deviant's position, the degree to which the deviant interferes with group goal attainment, and the group's openness to alternative perspectives. Research suggests that in general groups will try hard to socialize and include marginal members – marginalizing and rejecting members only as a last resort. Deviation from the group's normative practices may raise questions about what the group stands for, thus posing a threat to the group and its identity.

Research on reactions to deviance has also focused on the intergroup context. Much of this work focuses on the 'black sheep effect' – dissenting ingroup members are rejected and evaluated more negatively than a similar member who belongs to an outgroup. However, a different process occurs when a member not only is a deviant member but also actively criticizes the group norms. In this case, it is the outgroup member that is rejected by the ingroup (Hornsey, 2005), or a collection of such 'rejects' may schism from the parent group (Sani, 2005).

Group Performance

Groups often exist to accomplish a specific task. Group performance is the process and outcome of members' efforts to create a joint product or complete a task in which they all have a stake. When people combine their energies and coordinate their efforts, they can accomplish goals that would overwhelm an individual, however, people working together can also encounter problems coordinating and maximizing their efforts. An important question to ask is whether groups perform better or worse than individuals. The answer to this question depends on the specific nature of the task – social facilitation tends to occur when tasks are simple, whereas social interference occurs for tasks that are complex.

Social Loafing and Social Dilemmas

Although group interactions can improve overall group productivity, most research on group performance has focused on social interference in the form of process loss – reduction in performance caused by factors (e.g., reduced effort, coordination problems, and faulty group processes) that prevent the group from reaching its full potential. Two sources of process loss are coordination loss, which occurs when members are not able to organize their actions in an ideal way within the group, and motivation loss, which occurs when group members do not exert maximal effort on a task.

Social interference research has generally focused on 'social loafing' which occurs when people exert less effort while working together than while working alone. 'Social impact theory' and the 'collective effort model (CEM)' suggest that the social loafing effect is partially due to a reduction in perceived personal identifiability and accountability, task attractiveness, and responsibility within the group. Most research on social loafing has focused on eliminating or reversing its effects by, among other things, increasing task importance, relevance, enjoyment, group cohesiveness, and personal identifiability. Similar to loafing, 'free-riding' is a tendency for group members to contribute less to a group task when they believe that other group members will compensate for this lack of effort.

Group life by its very nature creates 'social dilemmas,' situations in which individuals can maximize their own short-term gains by acting in one way, with little regard for the long-term greater good of the collective. Because social dilemmas are so common in everyday life and group members often respond to them by seeking to maximize their short-term individual welfare, researchers have searched for ways to increase the likelihood that members will cooperate rather than compete. Evidence indicates, for example, that social dilemmas can be (partly) avoided when group members view their contributions as critical, when they communicate with one another, and when the group has a system for punishing people who refuse to cooperate. Additionally, leadership can serve to reduce the negative impact of social dilemmas; that is, leaders can transform selfish individual goals into shared group goals by building a sense of common identity, shared fate, and responsibility for the collective good.

The Crowd, Deindividuation, and Collective Behavior

Group dynamics research is based on the core assumption that people in a group act collectively. Although collective action usually takes place in small groups, people sometimes join larger collectives such as crowds and social movements. A crowd is a specific type of collective in which individuals share a common focus of interest and are concentrated in a single location (i.e., an audience, a mob, or a riot). Beginning with LeBon in the late nineteenth century, early theorists and researchers largely assumed that crowds are unique social aggregations where antisocial, violent, and impulsive behavior is the norm. These theorists argued that crowds are governed by a primitive collective mind that turns people into unreasonable, extreme, and impulse-driven followers. Early social psychological perspectives emphasized the power of the group and assumed that being a member of a crowd lead to 'deindividuation,' a psychological state characterized by reduced self-awareness and personal identity salience that had negative consequences for behavior.

Many contemporary theorists, rather than assuming that collectives are atypical groups that are out of control and normless, argue that collectives are at their core, groups and so the processes that shape group behavior also shape 'collective behavior.' Normative interpretations of collective behavior suggest that like any other group behavior, members of a collective adhere to norms (that could either be prosocial or antisocial). Additionally, social identity perspectives suggest that collectives are intergroup phenomena and that people in collectives do not experience a loss of identity rather their social identity is augmented in these situations. Collective behavior, similar to other group behavior, is a rational attempt by

a group to seek change through unified action. Research suggests that people engage in social movements and associated crowd events because they feel a sense of injustice, have a higher sense of efficacy, and identify with the group and its purpose.

Group Decision Making

One of the most common and important activities that groups perform is making decisions. Groups often make better decisions than individuals because in a group there is a larger pool of expertise, viewpoints, and so forth. Groups may come to a decision slowly; however, they are likely to make use of group procedures that enhance the way they gather, analyze, and weigh information. According to the functional theory of group decision making, groups generally follow the same processes or steps when they make a decision. The group first identifies the problem, sets goals, and develops a strategy in the orientation phase. Next, during the discussion phase, the group gathers information and considers the options. In the decision phase, the group chooses its solution by coming to a consensus, voting, or using another social decision process. Finally, in the implementation stage, the decision is put into action and the impact of the decision is assessed. Although groups have greater informational resources and the potential to outperform individuals, during the group discussion phase they are also subject to an array of group processes that may impair decision making such as conflict between group members, biased leadership, and conformity pressures.

Groupthink and Group Polarization

Groups sometimes employ deficient decision-making procedures that produce poor decisions. 'Groupthink' is one such poor decision-making process in which the desire for unanimity overrides the motivation to consider rational alternative courses of action. Several factors lead to groupthink and its corresponding symptoms including high group cohesiveness, impartial leadership, insulation from external information, and stress from external threat. Groupthink can have disastrous ramifications, and has been identified as the cause of many poor crisis decisions made by governments; for example, the 1961 Bay of Pigs fiasco (the failed attempt by the United States to invade Cuba and overthrow Fidel Castro's regime thought to be the result of a flawed decision made by President Kennedy and his advisors). There is only partial empirical support for groupthink and more recently researchers have proposed alternative groupthink models. The group centrism approach claims that groups whose members strive to maintain unity and have a high need for closure are more likely to make poor decisions. Another model proposes that negative decisional features previously thought to cause groupthink combined with shared social identity, restrictive norms, and lack of confidence will trigger groupthink.

Another potential bias in group decision making is 'group polarization,' a tendency for group discussion to cause the group and its members to shift to a more extreme position than initially held by the individual members. Polarization occurs when the prediscussion group preference tends to favor one pole of the decision-making dimension. The group decision is then more extreme in this direction. Social comparison (normative influence) processes, exposure to persuasive arguments (informational influence), and social identity processes are offered as explanations for group polarization.

Group Remembering

Another important component of group decision making involves the collective recollection of information – group remembering. Groups generally recall more than individuals on simple tasks because groups draw on more memories that contain different types of information. But groups tend to remember less than individuals on complex tasks, likely because of process loss. Group remembering is more than a simple collaborative recall, rather it is a constructive process whereby social comparison processes among group members shape collective memory. Thus, group memory is subject to social influence processes which may lead to group decision making bias (i.e., some individuals' memories will contribute to the developing consensus while others' will not). Additionally, group memory may be weakened by social loafing and by the complexity of the group setting which disrupts group members' ability to organize and retrieve information.

Another feature of group remembering is 'transactive memory.' Groups, like individuals, have memory systems that collect, encode, store, and retrieve information. Because groups generally have to process large amounts of information when making decisions, groups share the memory load so that each individual is responsible for remembering only part of what the group needs to know, but all members know who specializes in what memories. Transactive memory involves uneven distribution of memory in a group, and although it helps to improve overall group functioning and decision making, one potential problem is that when a group member leaves there is a temporary loss or reduction in group memory.

Intergroup Decision Making

Decision-making groups may contain individuals with opposing views, or can be considered to be interactive decision-making contexts in which opposing groups or their representatives come together to reach an agreement. In this situation, the group is a context for intergroup decision making. In this context, individuals act as group representatives rather than individuals. Thus they tend to bargain more fiercely and are less compromising than if they were bargaining for themselves. Intergroup decision making often ends in deadlock. Third party mediation may help resolve a stalemate but only if the mediator has power and is seen by both groups to be impartial.

The Intergroup Dimension

Historically, the study of group processes focused on what happens among members of small interactive groups and did not fully recognize how the relations between groups impacted intragroup processes. More recently, scholars have begun to incorporate intergroup perspectives in their understanding of intragroup processes. For instance, group polarization may be

an intergroup phenomenon in which a relatively extreme ingroup differentiates itself from a less extreme outgroup by becoming even more extreme. Intergroup processes can also affect leadership. For example, leaders not only lead their groups, but in some ways they lead their group against other groups. They must also bridge group divisions by building social harmony, a common purpose, and a shared identity. Also, extreme behavior in crowds may be best explained in terms of intergroup conflict – the crowd is a group with a common purpose which is directly in opposition to an outgroup.

Future Directions

There has been a marked resurgence of interest in social psychology in group processes. The rise in popularity of group research has been attributed to an integration of small group, intergroup, and cognitive perspectives in social psychology that sets the groundwork for promising future developments. The increase in popularity of online communities and public interest groups presents new and unique avenues for valuable research and insight. In the future, online group researchers will have to integrate their findings with theory and data from traditional face-to-face groups. Additionally, small groups research seems to have been taken over by organizational behavior programs in business schools and industrial–organizational psychology programs. Thus group research on understanding and improving the performance of work teams will likely remain strong in the foreseeable future.

Abstract

Group psychotherapy is the treatment of psychological, behavioral, emotional, and interpersonal problems by a mental health professional who meets regularly with clients in a group rather than a one-on-one context. Group psychotherapy is used to treat a variety of disorders, including addiction, cognitive disturbances, depression, eating disorders, characterological disorders, and many more, using methods that are as varied as those used in individual approaches. Multiple group-level factors, including instilling hope, social learning, social support, and self-insight, operate to promote adjustment in psychotherapy groups, and research suggests that this treatment technique is as effective as more individualized methods when properly administered.

Like any other form of therapy, group psychotherapy is designed to help clients overcome debilitating psychological and interpersonal problems. But unlike individual therapies, group therapies involve treating individuals in groups, with the group and its members providing resources for achieving positive personal change. When this treatment modality was initially proposed, many questioned the wisdom of promoting mental health by encouraging guided interactions between individuals suffering from psychological problems, but experience and research affirmed its efficacy. Note, however, that group psychotherapy is a treatment for individuals rather than groups. Group therapists are mindful of the interpersonal processes that operate within the group and may deal with the group as a whole, but they are not seeking to treat the group per se: They seek to promote the adjustment of the individuals in the group and with the support of the group.

Approaches to Group Psychotherapy

Group psychotherapy emerged as a means of helping people deal with psychological problems in the early years of the twentieth century. Clinical psychology itself was developing during this period, but most early psychotherapists worked with patients in one-on-one sessions only. Some innovators, however, applied their basic change principles in group settings, as did some therapists who turned to groups for didactic purposes or because their patient load demanded a massed approach to treatment. These group applications were often confined to a particular psychiatric facility or clinic, but in time they became more dispersed as other mental health professionals heard of and made use of group methods. These early psychotherapy sessions involved treating individuals "in groups, with the group itself constituting an important element in the therapeutic process" (Slavson, 1950: p. 42).

Group psychotherapy is used currently to treat a variety of problems, including major depressive disorder, bipolar disorder, panic disorder, posttraumatic stress disorder, social phobia, obsessive-compulsive disorder, bulimia nervosa, binge-eating disorder, substance use disorder, schizophrenia, borderline personality disorder, and general personality disorder (Burlingame et al., 2004). Group psychotherapists are usually mental health professionals, and their patients tend to be suffering from diagnosed clinical conditions. The methods used by group psychotherapists are as varied as individual approaches to therapy. Some therapists, for example, are primarily psychoanalytic in orientation, for they focus on pathological personality, characterological disorders, and deep-seated psychological conflicts. Others, in contrast, adopt a more interpersonal perspective that stresses the exploration of the social processes that unfold in the group. Other approaches are more behavioral; they teach group members specific behaviors they can use to cope with the problems they are facing. Most therapists, however, are eclectic: They base their work on a melding of many theoretical perspectives (DeLucia-Waack and Kalodner, 2005).

Psychoanalytic Group Psychotherapy

Psychoanalytic group psychotherapy draws on Freud's (1922) conceptualization of the causes of dysfunction and his recommendations regarding the most effective way to treat those dysfunctions (*see* Psychoanalysis in Clinical Psychology). The analyst, after establishing an enduring, supportive relationship with the patient, uses questioning, free association, and interpretation to stimulate self-insight, transference, and the cathartic release of unconscious anxieties and characterological conflicts (Shedler, 2010). The psychoanalytic group therapist, however, takes advantage of the group setting to help patients deal with hostilities, needs, and wants that are repressed in everyday interactions but surface in the group setting. As Freud's (1922) replacement hypothesis suggests, the group becomes a surrogate family with members serving as symbolic siblings and the group therapist acting as the primal authority figure. As transference develops, the group provides the therapist with the means of exploring the childhood roots of current adult anxieties. Members may react to one another inappropriately, but in ways that parallel their responses to people they know in their everyday lives. Some therapists are more fully Freudian in their orientation than others, but rare is the therapist who does not deal with transference processes, familial tensions, and other latent conflicts.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21066-0

Psychoanalytic group psychotherapists diverge on one key aspect of the process. Some stress the importance of the individual in the group. This approach argues that the therapist should stress individual-level processes in treatment, and avoid spending treatment time exploring the dynamics of the therapeutic group. Others, in contrast, integrate the treatment of the individual with the analysis of the group itself. The group-as-a-whole approach, which can be traced to the British psychotherapists at the Northfield Military Hospital in England, is a sterling example of this approach (Harrison, 2000). Although group-as-a-whole therapists embrace psychoanalytic assumptions of unconscious motivations, personality conflicts, and transference, they make use of the tension between the group and the individual to promote growth and development. Bion (1959), for example, stressed the analysis of defense mechanisms used by groups to cope with ego threats, uncertainties, and anxieties. He believed that these strategies are rooted in dependence, for the group members engage in collective projective identification as they struggle to avoid blame for their problems by shifting responsibility from themselves to the therapist. Bion assumed that rapid and lasting adaptive change could be achieved by helping group members understand both individual and collective defensive processes that unfold in their group session, and his work provided the basis for the Tavistock Institute of Human Relations (Conci, 2011).

Cognitive–Behavioral Therapy Groups

Cognitive and cognitive–behavioral psychotherapists, rather than searching for the cause of the problematic behavior in unseen unconscious conflicts or interpersonal transactions, base their interventions on principles derived from learning theories (*see* Concepts and Methods of Cognitive Therapies). They identify and quantify desirable cognitions and behaviors that will be encouraged and undesirable cognitions and behaviors that will be extinguished, and then modify these behaviors through cognitive restructuring, self-instructional training, and problem-solving instruction.

Cognitive–behavioral therapy groups use these principles with two or more individuals (Hollon and Beck, 2004). Cognitive–behavioral group therapy is generally both structured and problem focused. Prior to treatment, the therapist observes the reactions of each member to the group to index the degree of functioning and reviews the theories and procedures that sustain the intervention to clarify expectations and goals. Therapists can also use public commitment to these goals to enhance the binding strengths of a behavioral contract that describes in objective terms the goals that the group members are trying to achieve. During the therapeutic sessions themselves, the cognitive–behavioral group therapist can capitalize on the presence of multiple actors to magnify the effects of modeling, rehearsal, and feedback. Members of the group can practice interpersonal exchanges with other members, and other members can act as observers. These sessions can be recorded and reviewed so that the participants can see what they are doing correctly and what aspects of their behavior need improvement. During this feedback phase, the leader offers reassurance and praise, and members add their support and encouragement.

Interpersonal Group Psychotherapy

Many group psychotherapists not only exploit the social processes that occur in groups during treatment but also trace psychological disturbances back to social sources – particularly interactions with friends, relatives, and acquaintances. Interpersonal theorists assume that dysfunctional behaviors result from individuals' failures to take note of, and correct, cognitive and behavioral tendencies that disrupt their relationships with other people.

Many group therapists, recognizing the interpersonal bases of psychological problems, use the group setting to help members examine their interpersonal behavior. Yalom's interpersonal group psychotherapy (also called interactive group psychotherapy), for example, stresses the "here-and-now" of the group's interaction over the analysis of events and experiences that occur outside of the group (the "then-and-there"; Slavin, 1993). Members may spend some time, especially early in the group's life span, discussing problems they are facing at home or work, but Yalom feels that much of this discussion will be futile since members characterize such events inaccurately. Yalom instead recommends that members focus on interactions within the group, with each member eventually responding to one another as they do to others in their lives. The group thus becomes a "social microcosm," giving members true insight into the causes of the personal problems (Yalom and Leszcz, 2005).

Existential and Humanistic Psychotherapeutic Approaches

Another set of perspectives within the broad field of group psychotherapy draws on clinical and personality theories that stress the existential, self-reflective roots of adjustment and disorder. Humanistic, third-force theories such as person-centered theory, psychodrama, Gestalt, and human potential groups assume that individuals are, at their core, searching for ways to improve their current functioning and maximize their potentialities. Such approaches are often phenomenological and experiential, and they underscore the importance of a strong, positive, and empathic therapeutic environment for facilitating personal and collective growth.

Perls (1969), for example, frequently conducted Gestalt therapy sessions in groups. Members observed one another's 'work,' and they engaged in interpersonal exchanges with one another as Perls orchestrated the experience. In Gestalt groups, therapists frequently use unstructured interpersonal activities to stimulate members' emotional understanding (Gaffney, 2012). For example, a member will sit apart from the others and spend time publicly working through his or her understanding of an emotionally difficult experience (the 'hot seat'), or imagine that another person or a part of him- or herself is sitting in an empty chair and then carry on a dialogue with the person (the 'empty chair'). These techniques, when properly applied, can trigger strong emotional reactions, but Gestalt therapists resist offering direct interpretations to their patients (Greve, 1993).

Psychodrama, developed by Moreno (1953), also makes use of exercises to stimulate emotional experiences. Moreno conducted therapeutic groups perhaps as early as 1910, and he used the term "group therapy" in print in 1932 (Hare and

Hare, 1996). Moreno believed that the interpersonal relations that develop in groups provide the therapist with unique insights into members' personalities and proclivities, and that by taking on roles the members become more flexible in their behavioral orientations. He made his sessions more experiential by developing psychodrama techniques. When role playing, for example, members would take on the identity of someone else, and then act as he or she would in a simulated social situation. Moreno believed that psychodrama's emphasis on physical action was more involving than passive discussion, and that the drama itself helped members overcome their reluctance to discuss critical issues.

Therapeutic Factors in Groups

Group methods were used, initially, because they are efficient: Services could be rendered to many rather than just a few. But group psychotherapy, as a practice, is also consistent with psychologist Kurt Lewin's law of psychological change: "It is easier to change individuals formed into a group than to change any of them separately" (Lewin, 1951: p. 228). But what aspects of the group promote positive change? A common-factors perspective on group therapy suggests that various types of group psychotherapies, despite their many differences, share some common properties, and these commonalities may be responsible for their effectiveness (Forsyth, 2010). A psychodynamic therapist uses different techniques than a cognitive–behavioral or interpersonal therapist, but these various formats share mechanisms that promote change and sustain well-being. Yalom and Leszcz (2005) term these shared qualities curative factors, and their list includes the installation of hope, universality; the imparting of information, altruism; the corrective recapitulation of the primary family group; and the development of socializing techniques, imitative behavior, interpersonal learning, group cohesiveness, catharsis, and existential factors.

Social Motivation in Group Psychotherapy

Therapeutic groups are an informational resource for their members. The lone individual, experiencing some psychological difficulty, may misunderstand the sources of the problem and generate only a limited number of solutions or alternatives. But individuals who actively communicate with others experiencing similar difficulties can avail themselves of the relatively rich informational resources of the group. When assembled in a therapeutic group, members who initially felt they were uniquely challenged realize that the situation they face is shared by others. Yalom calls this realization universality, for patients realize that they have not been singled out to bear some extraordinary misfortune; rather, the problem they face is a universal one (Yalom and Leszcz, 2005).

Therapeutic groups also capitalize on social comparison processes to stimulate growth and adjustment. Social comparison occurs when individuals spontaneously compare themselves to other people around them. This comparative process does not occur in individualistic therapies, for patients can only imagine how they are coping relative to others. In groups, in contrast, a patient learns both directly and indirectly about one another's functioning. These comparative data yield two useful consequences: First, comparison provides patients with a baseline to calibrate their own level of functioning and determine where they stand along the coping continuum. They may learn, through downward social comparison – comparing themselves to those in the group who are performing poorly – that their own situation is not as bleak as they originally assumed. Second, this comparison can increase their sense of optimism about reaching an improved level of functioning. Yalom terms this process the installation of hope. Whereas individuals facing unpleasant circumstances alone may feel discouraged and pessimistic, when group members recognize that others are improving their motivational levels rise (Yalom and Leszcz, 2005).

Interpersonal Learning

Much of the learning that occurs during psychotherapy is social in nature. A skilled therapist can shape clients' behaviors through feedback and selective reinforcement, offer support, and model appropriate cognitive and behavioral responses to difficult situations. But when therapy is delivered in a group context, the sources of social learning are multiplied. Group psychotherapy necessarily involves patients interacting with other patients, and so it sets up opportunities for interpersonal learning among patients. Some therapists purposely minimize the impact of the group on the individual patients, but most group therapists exploit these social processes to promote change.

Interpersonal therapies assume that much of the curative power of a group springs from such social processes as imparting information from one person to another (guidance), the development of socializing techniques, imitative behavior, and interpersonal learning (Forsyth, 2010). For example, the exchange of information among participants was one of the first purposes of groups; these group therapies were primarily didactic in nature, with psychotherapists lecturing to large groups of patients about mental and physical health. Interpersonal learning also occurs indirectly, as members monitor their impact on the other people within their group, and the psychotherapist helps them draw conclusions about their maladaptive interpersonal tendencies. Members also gain simply by observing others dealing with their difficulties. By watching others' emotional displays, problem-solving behaviors, coping strategies, and interpersonal maneuverings, patients acquire adaptive social skills.

Groups also provide their members with feedback about interpersonal effectiveness and shortcomings. Members often exchange corrective, and in some cases negative, feedback, but such exchanges are usually counterbalanced by substantial doses of congratulatory, positive evaluations. In interpersonal therapy, in particular, patients often act as they do in other social contexts, so much so that the behaviors that caused them interpersonal difficulties erode their relationships within the group. When their fellow group members and therapist call their attention to the parallel, patients gain insights into their own motives and emotions. Members who report a strong level of identification with the group are more likely to accept the group's influence.

Group Cohesion and Development

As therapeutic groups develop over time, members become closely connected to each other emotionally, developing bonds of friendship that are as strong as any they experience in nontherapeutic relationships. A cohesive therapeutic group offers members something that groups, in general, offer their members: social support. When people experience challenging, traumatic events, the risks of psychological and physical illness are elevated, but if they are members of supportive groups, they are often protected against these negative consequences (Wills and Ainette, 2012). Most people turn to commonplace groups such as friendship cliques and family for their social support, but members of therapeutic groups frequently help one another by providing advice, guidance, direction, and emotional support. A cohesive group accepts its members, and this feeling of acceptance is considered by many group members to be the most central benefit of group membership (Kivlighan and Tarrant, 2001).

The group's level of cohesion depends, in part, on its stage of development (Forsyth and Diederich, 2014). Early in the group, interactions tend to be superficial, but in time conflicts tend to surface. In most groups, these conflicts between members and the group therapist give way to the development of cohesion (Burlingame et al., 2011). This progression of emotional experience, although characterized in a variety of ways, generally follows the forming, storming, norming, performing, and adjourning pattern identified by Tuckman (1965). During the forming stage, members are uncertain how to behave, and they do not trust one another enough to disclose personal information or to admit they need help. During the storming stage, group members often find themselves in conflict over the purpose of the group, and they may withdraw from the group and the therapist. In groups where the leader takes a nondirective orientation, this conflict stage focuses on the leader's failure to 'take charge' of the interactions. During the next phase, norming, the group becomes more cohesive, as norms and standards emerge that dictate how each session will unfold. This stage makes the performing stage possible, where group members engage earnestly in the exchange of information that will help them achieve their therapeutic goals. In time, members must deal with issues of termination as the group adjourns. This movement from one stage to another is therapeutic, so much so that a group that does not move through these stages may not benefit its members (Yalom and Leszcz, 2005).

Corrective Emotional Experiences

Therapeutic change results not only from the dispassionate analysis of one's psychological problems, but also from the direct experience of emotionally charged situations and their resolution. When a therapeutic session triggers a strong emotional reaction, such as a heated argument between group members, an unexpected expression of dislike or hostility for an idea or an individual, or an unreserved flow of grief and sadness, members can work through this 'corrective emotional experience' to better understand the source of their emotional reactions and how they can better handle them.

Group settings provide members with a range of opportunities to express emotions in ways that promote, rather than undermine, their well-being. As the concept of catharsis suggests, holding in strong negative emotions, such as anger and frustration, is unhealthy, and group sessions provide opportunities to 'blow off steam'; in psychologically and socially favorable circumstances (Ormont, 1984). Release of emotions, however, is not the curative benefit, but rather the analysis of the emotion-generating experience and the constructive communication of emotions to others. Group sessions provide members with more effective ways to disclose their emotions and to discriminate the effects that their emotional expressions have on others (Ormont, 1999).

Self Processes in Therapeutic Groups

All psychotherapies stress the value of self-understanding and self-acceptance, and group psychotherapies are no exception. The guided interaction of therapy groups provides the members with a rich source of information about aspects of themselves, for when members observe the way they interact with others – say, by dominating the group interaction, constantly criticizing others, displaying strong emotions, or expressing concern for others' well-being – they come to realize that they are dominant, critical, emotional, or caring, respectively. Members may be concerned that the group may see them for what they are – and that this accurate appraisal may not match their own sense of self – but self-discovery is a key goal of most individuals seeking analysis (Kivlighan et al., 2010).

Groups not only encourage the growth of self-knowledge but also promote self-acceptance. A number of psychological problems, including depression, anxiety, alcohol abuse, masochism, and eating disorders such as bulimia, are rooted in a devalued self, but inclusion in a stable, supportive group tends to promote self-esteem (Leary et al., 1995). As Baumeister and Leary's belongingness hypothesis argues, all "human beings have a pervasive drive to form and maintain at least a minimum quantity of lasting, positive, and impactful interpersonal relationships" (1995: p. 497). Just as exclusion from a group can trigger a loss in self-esteem, so can inclusion in a group contribute to more positive feelings of self-worth. Therapeutic groups also sustain self-esteem by giving members an opportunity to help others (altruism).

The Effectiveness of Group Psychotherapy

When therapeutic groups were initially proposed, skeptics questioned the wisdom of putting people who are suffering from psychological problems together in one group (Lazell, 1945). How, they asked, could troubled individuals be expected to cope in a group when they had failed individually? And how could the therapist guide the therapeutic process in a group, given the subtle nuances that pervade one-to-one therapies? In time, however, the method gained widespread acceptance as therapists added group sessions, either to supplement or to completely replace their individual sessions. Group psychotherapy is currently used to treat all types of psychiatric problems, including addictions, thought disorders,

depression, eating disorders, posttraumatic stress disorder, and personality disorders (Burlingame et al., 2011).

But do members leave the group better adjusted than when they entered? Do groups help patients explore and gain insight into sources of anxiety, help them identify and practice behaviors that they can use to cope with sources of stress, and provide them with a way to develop the skills they need to interact successfully with others? Meta-analytic reviews, including those that take into consideration methodological rigor and therapist orientation, suggest that group approaches are as effective as individual methods. Burlingame and his colleagues, for example, statistically combined the results of hundreds of experimental, quasiexperimental, and correlational studies before concluding that researchers had been more diligent in their studies of cognitive–behavioral therapies, and their review indicated that such methods were superior to untreated control groups and equivalent in effectiveness to individual approaches (Fuhriman and Burlingame, 1994). These findings were generally sustained when Burlingame et al. (2004) summarized findings from 107 studies and 14 meta-analyses of the use of group methods for treating a range of disorders, including anxiety, eating disorders, substance abuse, and personality disturbances. These analyses indicated that group methods are better for some problems than others – particularly social phobia and substance abuse. Other reviews indicate that groups that generate higher levels of member-to-member interpersonal feedback and stronger working relationships among members were more effective than other methods. The use of pregroup preparation and providing a higher level of structure during early group sessions also improved outcomes (Barlow, 2013).

Burlingame et al. (2004: p. 652) concluded that "group psychotherapy is potent enough to be the sole or primary treatment for patients suffering from a psychiatric disorder," but this positive conclusion requires some qualification. First, the empirical evidence is not definitive (Bednar and Kaul, 1994). Whereas a number of reviews are positive, the "use of varied and undocumented therapeutic methods, with different types of clients, by therapists who differ in skills and experiences, in studies that too frequently lack valid measures and adequate controls, make[s] it difficult to draw firm conclusions" (Forsyth and Corazzini, 2000: p. 325).

Second, group approaches work better for some disorders than for others (Burlingame et al., 2004). In particular, in both outpatient and inpatient settings, individuals experiencing mood disorders (e.g., anxiety and depression) respond better to group psychotherapies than individuals experiencing other types of disorders (e.g., thought and dissociative disorders).

Third, too little is known about the psychological and social processes that sustain the changes that are produced by group therapy. Do group-level processes such as social influence (informational, normative, and interpersonal), group cohesion, group norms, and social networking operate to shape the structure and function of therapeutic groups? If so, how do these group-level processes combine to influence outcome? Which group-level processes are most responsible for attitudinal and behavioral change, and which are less critical? Researchers have only begun to answer these questions pertaining to the factors that mediate the treatment–outcome relationship.

Last, the changes brought about by group experiences may be more perceptual than behavioral. Group members frequently report achieving major insights into their behavior and are positive about the gains they have achieved, but objective indices of outcome are more contradictory. Self-reported insight is also related to actual improvements in adjustment. One review, for instance, identified 26 controlled studies of personal growth groups that (1) used both pretest and posttest measures, (2) met for at least 10 h, and (3) had a long-term follow-up (at least 1 month after termination). Summarizing these methodologically superior studies, the reviewers concluded that group treatments did result in enduring positive changes, but primarily on self-report questionnaire data and not on behavioral measures (Berman and Zimpfer, 1980). These and other findings suggest that groups are most useful in promoting changes when members themselves appraise the gains they have achieved through participation.

These significant caveats aside, the available evidence prompts a guardedly optimistic conclusion about the therapeutic use of groups. Groups often exert an unrelenting influence on their members. Nearly all human societies are organized around small groups, and these groups shape their members' psychological adjustment and dysfunction. Given their ubiquity, people generally respond positively when presented the opportunity to work in a group to achieve mental health goals. Indeed, the increasing popularity of self-help groups signals the need for treatments that take advantage of groups for promoting adjustment. Although the use of groups in business and educational settings was once considered innovative, individuals now expect to learn and work in group contexts.

Group psychotherapy is also an efficient therapy, for a single therapist can treat more than one individual at a time – a characteristic that is considered very valuable in healthcare systems that seek to minimize costs without cutting quality. Far more research is needed to analyze the nature of the therapeutic group and its impact on members, but given the powerful self-processes and interpersonal processes that such groups instigate and the positive findings already reported by researchers, groups should be considered a treatment of choice rather than a radical alternative.

Abstract

A 'group' refers to a bounded collection of interacting individuals who are functionally, cognitively, and structurally interdependent to various degrees. Groups also differ in the degree to which they are task- or sentiment-oriented and in which the members are unique or substitutable. Thus, friendship groups, clubs, crowd-sourcing groups, and teams are paradigmatically different types of groups. The sociological study of groups is dispersed in various university departments (ranging from social psychology and sociology to business and communications), but there is an important common theme: the collective phenomena that emerge in groups. The most important collective phenomena studies are 'social embedding' (including shared knowledge and reality, social identity, collective memory, belonging), norms, collectively induced motivations, and status structures. In turn, these phenomena have considerable influence on behavior, but this influence is more frequently studied by psychologists.

The Sociological Approach to Groups

In sociology, a group refers to a bounded collection of interacting individuals who are interdependent in various ways. The most prominent interdependencies that have been identified are functional, cognitive, and structural interdependencies (see Lindenberg, 1997). In a group, individuals are functionally interdependent with regard to the realization of one or more goals. For example, group members need each other to reach a common goal (task interdependence) and may also affect each others' outcome (cooperative outcome interdependence). They are cognitively interdependent with regard to their collective identity, memory knowledge, sense of reality, expectations, and perceptions. For example, members influence each other in the formation of expectations and depend on each other with their collective identity. They are structurally interdependent with regard to the effects of the ties between them. For example, each member is affected by the constellation of informal ties between other members or by different links due to division of labor among group members. The three interdependencies influence each other, but sociologists often differ in the degree to which they focus on one or more of these interdependencies at the same time.

Groups differ in important respects. Traditionally, sociologists distinguished between primary and secondary groups, mostly based on the distinction of relationships seen as constitutive of the group (close relationships for primary groups, impersonal relations for secondary groups). By now, it seems more useful to distinguish groups by their place in a two-dimensional space (see Figure 1). One dimension is the degree to which the specific identity of a group member matters (is the group member unique or, in principle, substitutable?). A second dimension is the degree to which the common goal is related to task fulfillment or sentiment. For example, in a friendship group, each member's personal identity is important and people cannot easily be substituted. In addition, the group is not linked to specific common tasks but mainly to the maintenance of common sentiment. Members in a social club (such as a faculty club) jointly create common sentiments and are not tied to specific common tasks. However, they may stay or leave and are thus fairly substitutable. A team (such as a research team) is oriented toward common tasks with close coordination of activities, so that the identity of each team member also matters. By contrast, in a crowd-sourcing group (such as the makers of open source software), there are common tasks but contributors can come and go, so that identity matters little. For all kinds of groups, the 'groupishness' of groups (also called 'entativity' or 'cohesion' and mainly a matter of cognitive interdependency) can differ, but the uniqueness of members is likely to be linked to greater groupishness than the substitutability of members. Maybe because of this diversity of types of groups, sociology has not developed a field of research dealing with groups as such. The departments in which groups are studied from sociological points of view are also varied (e.g., sociology, social psychology, management, business, organization studies, social movements, communications).

Individuals have needs that are satisfied by group membership, such as the need to belong (Baumeister and Leary, 1995), the need for meaning (Heine et al., 2006), and the need for

Figure 1 Two-dimensional group space with prototypical kinds of groups.

Figure 2 Schematic depiction of the study of phenomena related to groups.

status (Steverink and Lindenberg, 2006). However, the sociological study of groups focuses not so much on why people join groups but on the collective aspects related to such needs. For example, for sociologists, belonging is not an individual state but a joint product of interacting individuals just as, for them, memory is mostly a collective phenomenon. Thus, in the work of sociologists, all kinds of groups are seen as giving rise to durable or semidurable collective phenomena (such as social embedding, social norms, patterns of motivation, status structures). These collective phenomena, in turn, influence the behavior of individuals and their interactions, such as performance, conflict behavior, creativity, openness to information, etc. (see **Figure 2**). Most of the sociological work deals with relation 1, some deal with relation 2 and some deal with relationships 1 and 2 (as well as other combinations). Relation 3b allows explicit feedback mechanisms involving both levels (as in expectation states theory, see below). Psychological studies of groups focus more often on the direct influence of interaction (or the presence of others) and on attitude change, productivity, satisfaction, self-esteem, depression, etc., occasionally allowing for feedback mechanisms (3a and 3b). The extra arrows (i) indicate exogenous factors (such as genetic dispositions, rules, established categories, and externally established status differences).

Historical Background of Small Group Research

The scientifically serious investigation of groups in the sociological tradition started with anthropological studies of tribes, clans, and families in the nineteenth and early twentieth centuries. Sumner, Durkheim, Simmel, and Cooley were early codifiers of this research. The most important turn in this development occurred in the 1930s. Within the span of a few years, five great books appeared, which had two very important messages in common: that groups are constituted by a cognitively mediated functional interdependence between individuals, that is, people who are dependent on each other for achieving some goal (including common sentiment) interact and something important happens to their minds and the way their minds operate when they interact. In addition, the actual situation in which their action is placed matters most for behavior (as opposed to traits or other cross-situational constants). This point was elaborated in various ways by a number of important books. In 1932, Alfred Schütz published *Der sinnhafte Aufbau der sozialen Welt* (*The Phenomenology of the Social World*). In 1934, Mead's (then already posthumous work) *Mind, Self and Society* appeared. Two years later, Lewin's *Principles of Topological Psychology* and Sherif's *The Psychology of Social Norms* came out. A year later, Parsons' *The Structure of Social Action* made its appearance. Merton's early work on reference groups was also quite influential in this regard. From this time, group studies continued in two traditions: experimental and field studies; both traditions bore the mark of this convergent conception of groups. Under the leadership of Lewin and Sherif, 'group dynamics,' as the experimental study of groups was then called, achieved great heights. Field studies had Mayo's Hawthorne studies and Whyte's famous *Street Corner Society* as models. Both traditions owe their success to the simultaneous consideration of the three fundamental interdependencies in groups: functional (related to goal achievement), cognitive (related to common categorizations, shared beliefs, and knowledge), and structural (related to the configurations of social relations). See Lindenberg (1997) for more detail on these interdependencies. However, the precise nature of the interdependencies was not yet well investigated and in the late 1950 and early 1960s, specialized groups of studies on each of these interdependencies became dominant, with interesting crossovers between psychology and sociology. Homans (1950, 1958), a sociologist, combined both field and experimental traditions in the study of functional interdependencies in exchange relations. Inspired by Homans, two psychologists, Thibaut and Kelley (1959), developed the study of small groups as the study of functional interdependencies. Their book is to this day one of the best on the subject. It influenced Homans' further work on the subject (Homans, 1961). Cognitive interdependencies were elaborated by Sherif and turned into a major strand of group research called 'Social Identity Theory' by Tajfel (1982) and Turner (1982), both psychologists but very influential among sociologists and in turn influenced by sociological symbolic interactionism. In a related development, Moscovici, a psychologist,

elaborated Durkheim's theory of collective representations (see Flick, 1998). Berger and Luckmann (1967) elaborated the social construction of reality and Goffman (1961, 1974) showed how this construction might take place in social interaction. Structural interdependencies were more formally elaborated by the psychologist Cartwright and the mathematician Harary and turned into a full-blown network approach by sociologist White and his followers (see White et al., 1976). This approach is now often combined with the exchange approach.

Collective Phenomena That Emerge in Groups

Because for sociologists the emerging collective phenomena are the most important aspects of groups, the remainder of this overview will discuss such collective phenomena. Studies of social dilemmas are covered elsewhere. Due to space restrictions, the reader will be referred mainly to 'collections' rather than individual works.

Groups and Social Embedding

Often, just differences in labeling groups of strangers will induce an instant tendency to favor the 'in-group' (Durham et al., 2011). Individuals need to belong. For sociologists, a particularly interesting aspect is that belonging is not just an individual need and its satisfaction, but a product of processes of social embedding. There is also an epistemological need for shared reality and groups provide such a reality. An individual experience remains ephemeral until it is recognized, shared, and mutually confirmed (Kruglanski et al., 2006). As groups develop, they will engage in activities that make the group recognizable and special, supplying a shared reality (including shared knowledge and collective memory) and collective identity, and often setting the 'in-group' off against 'out-groups.' An important instrument for bringing this embedding about is what Fine (1987), in a famous study on Little League baseball teams, has called 'idioculture.' It consists of shared knowledge, beliefs, behaviors, and customs, such as jokes, nicknames, slang, superstitions, rituals, and taboos. An important part of this process is the emergence of the collective memory, together with ceremonies and commemorative objects (Misztal, 2003; Olick et al., 2011). Sociologists have studied processes that make belonging, shared reality, knowledge, and memory joint products in all sorts of groups: music bands, work groups and teams, sports clubs and teams, primary care units, educational groups (e.g., school classes), and more loosely structured groups, such as social worlds and Internet groups (see, e.g., Engestrom and Middleton, 1998; Lim et al., 2011). Much of group-related ethnographic research in sociology is focused on these processes and much of it is said to be based on 'grounded theory' (see Charmaz and Bryant, 2007). Grounded theory means many things but in this context it refers mainly to four interrelated features: firsthand data collection (as in ethnography); a high degree of contextualizing (i.e., the constant search for social embeddings); varying the (sub)categories used for coding observations in order to facilitate discovery; and moving back and forth between data, analysis, and emerging theory.

There are also quantitative approaches to shared cognitions. For example, the study of 'shared mental models' quantitatively maps group members' similar mental models of content (say of a common task), of structure (say, networked associations of components of the task), and the degree to which the members' models are truly shared in content, structure, and realization of collectiveness (see DeChurch and Mesmer-Magnus, 2010). Yet another approach to social embedding focuses on coorientation (Scheff, 1967) or what is now often called 'interactive belief systems.' Here the emphasis is on the intertwining of (higher orders of) knowledge: "I know that you know that I know," etc. For the coordination of behavior in interacting groups and the development of trust (as a collective phenomenon), the development of coorientation has been identified as vital (Moldoveanu and Baum, 2011). What is taken for granted in game theory (there referred to as 'common knowledge'), is for sociologists an important group product all by itself. Related studies deal with certain aspects of collective knowledge and memory referred to as 'transactive memory' (Hecker, 2012; Lewis and Hemdon, 2011). The idea is that group members can mutually reinforce each other's memories of facts, events, and expectations that are collectively deemed important, which, in turn, increases coorientation and thus communication, trust, and coordination. Another kind of transactive memory refers to distributed memory whereby group members individually remember different things so that the total memory capacity of the group is greatly enhanced (Gupta and Hollinghead, 2010).

The development of social embedding depends in part on the heterogeneity of groups. A growing number of studies focus on such preconditions of the development of collective group phenomena (see, e.g., Chatman and Flynn, 2001; Flache and Mäs, 2008). Such studies are important complements to the studies that focus on social embedding.

Groups and Norms

Groups are the primary producers of social norms (Hechter and Opp, 2001). There are four important kinds of norms. First, norms develop for social embedding in groups. They are specific to the group and help create a social (i.e., group) identity, increasing groupishness and making each group special and different from other groups (see above). Examples are norms about attitudes toward certain out-groups; norms about religious beliefs; norms about what is and is not funny; norms about clothes, hairstyle, and form of greeting. Second, there are norms about positive and negative externalities, such as helping and not hurting others. In contrast to the embedding norms, such norms are often quite general in content across groups (e.g., about helping in need) but specific with regard to the circumstance of application (what constitutes need) and with regard to legitimately expected sacrifice for conforming to the norm (see Lindenberg, 1994). Third, there are norms that deal with the fact that groups have common goals and that attainment of these goals must be facilitated by consensual rules and norms. For example, for teams, there are norms that regulate roles, cooperation,

coordination, and conflict (Mathieu and Rapp, 2009). What are the different roles and responsibilities? How are they related to the common task? When is it necessary to consult others? Who is responsible for completing certain activities? How often and when will individuals meet to discuss issues relating to reaching their common goals? How should conflicts be resolved? Fourth, there are 'metanorms.' They regulate the applicability of and conformity to all sort of norms (such as norms on externalities and norms about the severity of deviance and about desired reactions to deviance, Lindenberg, 1994); and, importantly, they regulate collective memory: (what needs to be remembered, what forgotten). Norms on collective memory also pertain to all three groups of norms (e.g., to remembering commemorative events, feasts, and losses) but also to externalities (when should what effect on others be remembered) and to reaching common goals (such as details of the work design and distribution of responsibilities in teams).

Sociologists have also dealt with 'ghost norms' that are based on a false consensus, in the sense that everybody thinks they apply, whereas everybody believes himself or herself to be the only one who does not subscribe to them. For example, in groups, many members might believe that heavy drinking is expected by the others even though they do not support such a norm themselves. The driving force behind the stability of such ghost norms is a perverse product of an important feature of the stability of norms in general: the metanorm that if you believe that something is an important norm, then you should give social approval to others who follow the norm and disapproval to those who don't, even if you don't subscribe to the norm yourself. In this way, the others interpret your behavior as endorsement of the norm (see Willer et al., 2009).

Groups and Motivation

The motivation to follow group norms and to be oriented toward group goals has been an important subject in group research. Traditionally, in sociology, norm conformity has been linked to socialization processes, in which persons learn to want to do what they have to do. By contrast, modern rational choice explanations maintain that people conform to a norm when rewarded for doing so and punished for not doing so. However, the cognitive interdependence that has long been central to the study of groups leads to a different view – one that has been elaborated in social identity theory, and in cognitive sociology and social psychology. Even though rewards and punishments are important, it is people's ability to identify with group goals ('We' rather than 'I') and the activation of this orientation through cues in the environment that are the major drivers of norm conformity (especially where people are not monitored). Thus, studies that are concerned with the processes of identity formation in groups (Tyler and Blader, 2003; Postmes et al., 2005) and studies that deal with the activation of group orientation (see Lindenberg and Foss, 2011 for overview) have become most important for the explanation of norm conformity in groups. Processes that increase people's social identity will increase their sensitivity to demands relating to group goals and norms (Simpson, 2006). The same will be true for cues that increase a 'normative goal frame' (Lindenberg and Foss, 2011). Much group-related research thus focuses on the conditions that lead to a strengthened group orientation. For example, fairness of procedure and outcomes will strengthen social identity (Tyler and Blader, 2003). Common rituals can serve the same purpose (Islam and Zyphur, 2009). True to the collective aspect of norm conformity, cues that others show respect/disrespect for norms are highly effective in strengthening or weakening a collective orientation (Keizer et al., 2008). This cue effect derives its power from the fact that it is not just limited to imitation (I don't help if others don't help), but that it 'jumps' across norms (e.g., observing somebody else not helping may induce stealing), called a 'cross-norm effect.' Another important influence on norm conformity is 'transformational' group leadership that does not motivate by contingent rewards but by vision, example, and care. Group leaders can develop and articulate a shared vision, they can serve as role models, and they can attend to the needs of group members, thereby increasing trust in the group's collectivity and cohesion (Wang et al., 2011).

For task groups, there is an extra kind of motivation that relates to the joint production of a valued result. The classical example is collective barn raising in villages where all chip in to get the project done. Seemingly, we are hardwired to be especially dedicated to what we perceive to be a common task with individual responsibilities (Lindenberg and Foss, 2011). This contrasts with sentiment groups ('community'), in which there are no individual responsibilities and thus there are the possibilities of depersonalization and social loafing when common tasks suddenly appear (Williams and Karau, 1991). For the special motivation for joint production to occur, the collective orientation must be high (as for sentiment groups). However, in addition, the task must be clear and well understood in order to create a clear picture of one's own responsibilities in relation to those of others. For this reason, increasing the understanding of not just one's own role but also that of others ('cross understanding') is an important contributor to the motivation for joint production (see Huber and Lewis, 2010).

Groups and Status Hierarchies

One of the best-studied collective phenomena with regard to groups is the formation and maintenance of status structures. There are two main approaches that should be distinguished and both apply particularly to task groups. One is based on expected differences in the ability to contribute to a common task (expectation state theory); the other is based on inequalities of resources in social exchange. Expectation state theory (see literature in Berger and Zelditch, 1998) has a long-standing research tradition in sociology. In this theory, following the tradition of Bales in the 1950s, factual power and prestige are conflated and their combined structure is conceived in terms of behavioral aspects (opportunities and influence) rather than the distribution of scarce resources. The higher a person is on the power and prestige structure, the more opportunities to act he or she receives, the more often he or she takes advantage of these

opportunities, and the more often he or she wins disagreements, if and when they occur. However, the basic mechanism that creates this structure lies with cognitive interdependencies: the pair-wise interaction (between, say, Ego and Alter) that is governed by performance expectations with regard to the common task. It is the (unobservable) structure of these performance expectations that keeps generating the observable power and prestige structure. When Ego has positive performance expectations regarding Alter, he or she will give more action opportunities to Alter; and Alter is more likely to take up each opportunity offered. Alter has influence over Ego. It is assumed that there is an evaluation bias. Ego is more likely to judge Alter's performance to be positive if the performance expectation was positive and vice versa. And if Ego nonetheless voices disagreement, he or she is more likely to eventually yield to Alter if the performance expectation was positive to begin with. Such evaluation biases greatly enhance the stability of the power and prestige structure in task groups (provided the task endures), without necessarily undermining the groupishness of the task group.

The link between functional (aspects of the tasks) and cognitive (performance expectations) interdependencies is made even stronger through extensions of the theory to include external status characteristics (see literature in Berger and Zelditch, 1998). Task groups are embedded in a wider culture in which such status and competence beliefs exist (such as 'men are better at mathematics'). People seem to follow the maxim "when in doubt, assume that a salient characteristic is task relevant (especially if it is diffuse, such as race or gender)" (Simpson and Walker, 2002). With regard to gender, this favors men in general tasks as well as in 'masculine' tasks, and it favors women only in stereotypically 'feminine' tasks (see also Webster and Rachotte, 2010). Newer developments are mainly concerned with the ways in which status beliefs arise in group contexts. Seemingly, performance expectations are not only generated by clear perceptions of competence or diffuse status characteristics imported from the outside, but also by persistent inequalities in resources (say rich or poor) that are mis attributed as causally linked to group success. In this way, nominal characteristics can become status characteristics (Ridgeway et al., 2009). A classical variant of these status-building processes (outside expectation state theory but compatible with it) has been suggested by Coleman (1961). He highlights the importance of intergroup rivalry for internal status hierarchies. For example, competitive sports teams in schools develop status hierarchies due to the players' contributions to success in intercollegiate competition.

Dependency Networks, Groupishness, and Individual Differences

Status differences in groups can also come about by a process that is independent of expectation states. As Blau (1964) has shown in a pioneering study, asymmetric exchanges among group members can lead to status structures in task groups. The central idea is that people cherish status and thus also cherish being called superior by others. This is likely to happen if a group member needs something from another group member but has nothing else to offer than to admit his or her inferiority and the superiority of the other (who cherishes this gesture and, in return, is thus willing to give up information or other valued resources). If exchanges are made among members who are unequal in resources, this can lead to inequality in exchange which, in turn, can lead to people claiming (and others accepting) superior status. Newer versions of this theory (in combination with the exchange theory by Emerson, 1976) deal mainly with power-dependency differences rather than status structures, even though some theorists link the two by using status effects to explain power-dependency effects (Thye et al., 2006). In contrast to status research, power-dependence research emphasizes functional and structural dependencies (especially dependencies due to possible exclusion) and de-emphasizes attention to cognitive interdependencies, as mutual perceptions play no important role (see Cook et al., 2006; Willer, 1999). Thereby they focus less on the group embeddedness of social networks than approaches that include cognitive interdependencies. Still, the structural emphasis has its own advantage in that it shows that the network structures (that are possibly embedded in groups) have their own considerable influence that may undermine groupishness in favor of gain-related and/or affect-related individual outcomes (Burt, 2002); and that this influence is mostly due to dependencies (Bonacich and Bienenstrock, 2009). The structural focus also shows that seemingly individual characteristics (such as being powerful, being successful, being a failure, having high or low self-esteem, etc.) can be collective phenomena generated by social structures. It is also evident that for fostering groups, pure power asymmetries do not work well, compared to generalized exchange structures (Willer et al., 2012). With generalized exchange, cognitive interdependencies (in the form of group identification) are more likely to emerge. As we have seen above, when there are power differences, it is the powerful members' contribution to group goals (best aided by transformational leadership) that can neutralize the negative effects of power differentials and stress positive cognitive interdependencies, thereby fostering groupishness (Wang et al., 2011). Finally, there is also research that deals with the reverse process: certain cognitive interdependencies (in the form of reflected appraisals of one's own position) can be the source rather than the consequence of power differentials within groups (Friedkin, 2011) that may or may not support groupishness.

In short, groups give rise to social embeddings, to norms, to collectively induced motivations, and to status structures. However, embedded dependency networks within groups and the resulting power structures may undermine groupishness to various degrees, producing instead structured differences in individual characteristics. Contributions to group goals by the powerful may neutralize this potentially negative effect of dependency structures.

Evaluation

Sociological research on groups mainly deals with collective phenomena that emerge in groups, such as social embedding (including belonging and identity, shared knowledge and

reality, collective memory), social norms, collectively produced motivation, and status structures. Ideally, the study of groups include attention to functional, cognitive, and structural interdependencies, but often the focus is only on one or two of these three structures. There is much productive research going on but, unfortunately, it is spread over a wide variety of university departments and journals, ranging from social psychology, sociology, management, business, to social movements, communication, and simulation journals. Groups themselves are presently not a 'field' in sociology, even though they are the wellspring of society's most important collective fabrics. A common field would make sense, given the communality among the various types of groups that are now dealt with as separate topics in the literature. It is the articles in encyclopedias that keep at least a semblance of a field called 'groups' alive.

This article is reproduced from the previous edition, volume 9, pp. 6439–6445, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

This article begins with an introduction of the intellectual history of the development of growth curve analysis since the 1750s. It then introduces the prevailing linear and nonlinear models for growth curve analysis for univariate as well as multivariable situations. It ends with a discussion of issues with growth curve modeling in the recent literature, especially how it relates to structural equation modeling, more general differential equation models, and Bayesian estimation.

The phrase 'growth curve analysis' denotes the processes of describing, testing hypotheses, and making scientific inferences about the growth and change patterns in a wide range of time-related phenomena. The term 'growth curve' was originally used to describe a graphic display of physical stature (e.g., the height or weight) of an individual over consecutive ages, and some early data collections are presented here. Techniques for the analysis of growth curves were initiated in the physical sciences, more fully developed in the biological sciences, and used in studies of the size and health of plants, animals, and humans. In the behavioral sciences, growth curve analyses have been applied routinely to a wide range of phenomena – from experimental learning curves, to the growth and decline of intellectual abilities and academic achievements, and to changes in other psychological traits over the life span. Formal models for the analysis of growth data are described in a nontechnical fashion including linear and latent growth models, nonlinear growth models, and multivariate growth models. This article includes recent historical developments, contemporary issues, and future directions.

In contrast to some longitudinal data, growth curves have unique features: (1) the same entities are repeatedly observed, (2) the same procedures of measurement and scaling of observations are used, and (3) the timing of the observations is known. Formal models for the analysis of growth curves were developed in many different substantive domains with a common goal – to examine and uncover a fundamental set of regularity conditions or 'basic functions' responsible for the manifest growth and change. Techniques for the analysis of growth curves were initiated in the physical sciences, more fully developed in the biological sciences, and then used in studies of the size and health of plants, animals, and humans. In the behavioral sciences, growth curve analyses have been applied routinely to a wide range of phenomena – from experimental learning curves, to the growth and decline of intellectual abilities and academic achievements, and to changes in other psychological traits over the life span.

Growth curve analyses are among the most widely studied and well-developed mathematical and statistical techniques in all scientific research. These analyses have roots in the seventeenth- and eighteenth-century calculus of Newton and probability of Pascal, but this article is limited to more recent historical developments and other related techniques, such as time series and dynamical systems analyses are not covered.

Growth Curve Data Collections

The first reported growth curve data were collected by the French Count de Montbeillard between 1759 and 1777. These data consist of semiannual measurements on the growth of the height of his son over nearly 18 years. The data were plotted by Scammon (1927) and are presented here in the upper curve of **Figure 1**. As Scammon reported,

> it will be noted that the curve shows the typical four phases which most modern students have observed in the postnatal growth in stature of man, and which are characteristic of the growth of so many parts of the body.
>
> p. 331

The first analysis of these data was by the naturalist Buffon in 1799 and

> should be given full credit for the discovery of seasonal differences in growth a full hundred years before the modern investigation of this work.
>
> p. 334

The lower growth curve in **Figure 1** is based on group averages obtained by Variot in 1908 and

> it is interesting to note that, while the absolute values of the two series are quite different, the general form of the curve is essentially the same in both instances.
>
> p. 335

These early growth curves were the precursor to an enormous collection of biological data on growth and change. A more recent illustration comes from the important work of Tanner and his colleagues (see Tanner, 1960). In the individual plots of height in **Figure 2**: (1) the 'velocity' or rate of change is plotted at each age and (2) these curves are plotted against their

Figure 1 The initial 'growth curves' of human height data from Scammon, R.E., 1927. The first seriatim study of human growth. American Journal of Physical Anthropology 10, 334. Note: The vertical (*y*) axis represents the height in centimeters and the horizontal (*x*) axis represents the age in years from birth.

own 'highest peak velocity.' This display demonstrated two interesting features of physical growth: (1) persons who start growth at the earliest ages also grow the most but (2) all individuals share a remarkably similar shape in their 'adolescent growth spurt.' Extensions of these basic findings on physical growth systems and the contrast of chronological time versus biological time are still used in contemporary research.

Experimental psychologists have routinely collected different kinds of growth curves. Among the first here were the classical 'forgetting' curves collected by Ebbinghaus in the

Figure 2 Alternative 'velocity curves' of physical stature from Tanner, J.M. (Ed.), 1960. Human Growth. Pergamon Press, New York, p. 22. Note: The left-hand graph shows the change in height as a function of the change in time (*y*) vs the age in years (*x*), while the right-hand graph shows the same curves (*y*) plotted around the time of maximum change in scores (*x*) for each individual.

Figure 3 The 'learning curve' of a cat from Thorndike, E.L., 1911. Animal Intelligence. MacMillan, New York; as reported by Garrett, H.E., 1951. Great Experiments in Psychology. Appleton-Century-Crofts, New York, p. 44. Note: The response time (*y*) required for a cat to escape from a closed box by pulling on a wire as a function of consecutive number of trials (*x*).

1880s, whose work introduced the use of quantitative methods in the study of learning and memory and stimulated many experimental data collections. Included here are the 'curves of improvement' in studies on telegraphic language by Bryan and Harter in 1897. These principles were also used in the animal learning curve experiments of Thorndike in 1911, and one example of such data appears in **Figure 3**. This plot illustrates an example of 'trial and error' learning: learning was objectively defined by decreasing response time and the lack of smooth function over trials was considered as error. Thorndike used these growth curves to illustrate several classical principles of learning, including the 'law of exercise' and the 'law of effect' (see Garrett, 1951).

Differential psychologists have also contributed growth data in many different substantive areas. One good example of this tradition is given in the plots of **Figure 4** from work of Bayley (1956). Individual growth curves of mental abilities from birth to 25 years are plotted for a selected set of boys and girls from the well-known Berkeley Growth Study. Because mental ability was not easily measured in exactly the same way at each age, these individual curves were created by adjusting the means and standard deviations of different mental ability tests (i.e., Stanford–Binet, Terman–Merrill) at different ages into a common metric. As Bayley says,

> they are not in 'absolute' units, but they do give a general picture of growth relative to the status of this group at 16 years … These curves, too, are less regular than the height curves, but perhaps no less regular than the weight curves. One gets the impression both of differences in rates of maturing and of differences in inherent capacity.
>
> 1956: p. 66

This use of 'linked' measurement scales created a novel set of growth data and permitted the use of growth analyses initially derived in other scientific areas.

Linear Models for Growth Curve Analyses

The simplest growth models are based on the simplest mathematical functions. The fitting of a straight-line to a set of measurements, a standard procedure in scientific research, was an initial model used by Wishart (1938) in a classic paper on growth analysis. These linear models were quite practical because the calculations used standard statistical assumptions (e.g., independence and normality of the residuals), standard forms of estimation (e.g., Gauss–Markov least squares, maximum likelihood), and standard statistical tests of goodness-of-fit (*F*-tests, chi-square tests, and likelihood ratio tests).

Another key idea was also introduced by Wishart (1938) when he showed how power polynomials could be used to

Figure 4 Growth curves of intellectual abilities in selected boys and girls from Bayley, N., 1956. Individual patterns of development. Child Development 27 (1), 67. Note: Age 16 D scores (*y*) plotted as a function of age at measurement (*x*) for (a) five boys and (b) five girls.

fit the nonlinear curvatures apparent in growth data. The individual growth curve (consisting of $t = 1$, T occasions) is summarized into a small set of linear orthogonal polynomial coefficients based on a power series of time (t, t^2, t^3, … , t^p) describing the general nonlinear shape of the growth curve. A model of growth data might require a second-order (quadratic), third-order (cubic), or even higher-order polynomial model fitted to the data, but the basic shape of each individual curve could be captured with a small number of parameters.

The organization of individual differences is an important consideration in any contemporary growth model. In the linear model, each individual is assumed to be following a straight-line over time, describable by an intercept term and a slope term. The average of these individual scores can be used to describe the overall growth curve for the group, and the individual differences can be considered in the context of other substantive questions, e.g., do the groups under observation differ in intercepts or slopes? In the more complex polynomial models, Wishart suggested a second stage of analysis where these polynomial coefficients describing each individual curve were considered as the underlying scores that covary among different individuals. In a quadratic polynomial, for example, a person's trajectory over time could be summarized using an individual intercept, linear slope, acceleration, and a residual term, and secondary questions could be addressed, e.g., do the groups under observation also differ in acceleration?

This 'curve-fitting' or 'two-stage' approach was relatively easy to implement using a standard statistical basis for hypothesis testing (e.g., Bock, 1975). The simplicity of this approach allowed linear growth models to enjoy widespread use in behavioral studies and become a useful starting point for understanding individual differences in change (e.g., Rogosa and Willett, 1985). The persistent critiques of this polynomial approach include some key issues:

1. The individual parameters can be difficult to estimate, especially for higher-order terms and incomplete data.
2. Even high-order polynomials (i.e., $p > 4$) cannot capture 'seasonality' or 'phase-shifts.'
3. The substantive meaning of these individual parameters is often in doubt.
4. The individual level parameters can be transformed (i.e., rotated) to yield alternative meaning.

These standard critiques are appropriate, and they still apply to many other contemporary forms of growth curve analyses.

More complex linear models have been used to represent growth. A linear model applied to different age segments but with connected critical 'knot points' permitted a 'conjoined' or linear or polynomial 'spline' model (e.g., Bryk and Raudenbush, 1992). This kind of spline model is not often used, partly because it is atheoretical, and partly because it may require a relatively large number of parameters to achieve adequate fit. A more parsimonious organization of individual differences was proposed in the form of 'latent curves,' independently defined by both Rao and Tucker in 1958 (cited in Meredith and Tisak, 1990). Principal components of the repeated observations were used to reorganize these data into the sum of a small number of unspecified linear functions that are fitted to growth data, the shape of the latent curves is determined by the component loadings, and the individual curve parameters are the component scores. The summation of latent curves has roots in the classical nineteenth-century work of Fourier as now widely used. In a recent innovation, Meredith and Tisak (1990) showed how these 'Tuckerized curve' models could be represented using confirmatory common factor analysis models, used to represent a wide range of alternative models (including most of the models discussed herein), and fitted using structural equation modeling techniques (also see McArdle, 1988; McArdle and Bell, 2000; McArdle and Woodcock, 1997).

Nonlinear Models for Growth Curve Analysis

The linear models can be used to describe a variety of nonlinear shapes, but many growth curve models for specific substantive problems have included nonlinear functions of the parameters. For example, Ebbinghaus in 1880 described his forgetting curves using a form of the classic 'exponential growth' model. Here the rate of change is a linear function of the percentage of initial size (e.g., compound interest), and individual trajectories rise or fall in nonlinear fashion toward some asymptotic values. In contrast, the nineteenth-century Velhurst curve of population growth, an S-shaped 'logistic curve,' was used in the early twentieth century by Pearl for many forms of growth. At about the same time, Peters advocated an 'ogival' curve of growth in ideational learning, Thurstone found that a hyperbolic curve of learning is best to fit the norms of many different tests, and both Ettlinger and Valentine demonstrated direct relationships among these functions (see Seber and Wild, 1989; Bock and Thissen, 1980).

More complex nonlinear models have been used extensively. In about 1825, Gompertz described the growth curve in terms of two exponential accumulations of different rates toward different asymptotes. This flexible model was studied in the first half of the twentieth century by Winsor, used by Medwar to study the growth of chicken hearts, and by Deming for human physical growth and in studies of learning curves (see Browne and du Toit, 1991). Another popular nonlinear model, introduced around 1938 by von Bertalanffy, suggested that an individual's change in weight was the direct result of the difference in the forces of anabolism and catabolism, with the exact relationship specified by known empirical properties. In subsequent work, Richards challenged the empirical basis of this model, and formally showed how many prior models can be seen as specific solutions of a 'family' of deterministic differential equations; specific restrictions led to the exponential, logistic, Gompertz, and von Bertalanffy equations. This work was more recently extended by Nelder and Sandland and McGilchrist (1979). (See also Seber and Wild, 1989; Zeger and Harlow, 1987; Tsoularis and Wallace, 2002.)

Attempts to fit a single growth model to observations over a wide range of ages with a minimal set of parameters led researchers to combine aspects of other models. Jenss and Bayley in 1937 proposed a simple composite where a linear part was used to fit the early rapid growth phase and this was added to an exponential part to fit negative acceleration of the later slowing-down phase. A more complex composite model, the sum of multiple logistic curves, was suggested by Robertson

in 1908 and Burt in 1937 but only made practical and fully developed by Bock and his colleagues (see Bock and Thissen, 1980). In each segment, the rate of growth (1) increases early, (2) reaches a maximum (peak growth velocity), (3) decreases toward the asymptote, and (4) the final value of one segment is used as the starting value of the next segment. A novel composite model based on multiple logistic functions was developed by Preece and Baines in 1978 and here the model parameters were supposed to be linearly related to meaningful biological parameters. Simple versions of this new family of curves have proven useful in contemporary work (see Hauspie et al., 1991).

The mathematical elegance of these nonlinear formulations often make it seem that the parameters estimated are related directly to the underlying phenomena and there is a tendency to treat these estimates with direct substantive interpretation. Prior research has shown this to be a difficult goal and now it is known that all models permit alternative formulations that may fit equally well. Another important property of growth curves comes when the fixed parameters of the nonlinear curves, the 'parameters of the means' also represent the 'means of the parameters' of the individual curves. However, classical research by Merrill in 1931, Estes in 1957, Tucker in 1966, and Keats in 1983 have shown this form of 'dynamic consistency' does not always hold, even for some of the most popular growth models (e.g., a group exponential). Contemporary statistical models are now constructed carefully to clarify the unique substantive interpretation of nonlinear parameters (see Browne and du Toit, 1991; Bock and Thissen, 1980).

Multivariate Growth Curve Analyses

The collection of multiple variables at each occasion of measurement leads naturally to questions about relationships among growth processes and multivariate growth models. In biological research, early efforts were directed at characterizing the parallel properties of different growth variables. Models were developed originally to deal with the size of two different organs, and an early nineteenth-century work was used by Huxley to form a classical 'allometric' model where two variables have a constant ratio of growth rates throughout the growth period. Many physical processes were subsequently found to grow in parallel, or in an ordered time-sequence (e.g., Tanner, 1960). This work led to more sophisticated models based on systems of differential equations for the size of multiple variables. In one comprehensive multivariate model, Turner in 1978 extended the simple growth principles to more variables and permitted an examination of biologically important interactions based on the size and sign of the estimated parameters (see Griffiths and Sandland, 1984).

Multivariate research in the behavioral sciences has relied on advanced versions of the linear growth models formalized by Rao, and Pothoff and Roy (see Bock, 1975). The structural models developed within this framework have added measurement models and this includes work on multivariate models of latent curves (McArdle, 1988). These structural models have proven useful in testing hypotheses about parallel growth processes across time in multiple psychological variables. In recent examples, McArdle and Woodcock (1997) showed how latent growth of a single common factor of intellectual abilities is a poor representation of multiple abilities data and McArdle (2000) showed how a multivariate dynamic sequence could be fitted using standard structural equations. Current research in this area is focused on an improved understanding of the time-sequences and interactions among multiple behavioral and biological variables (e.g., Li et al., 2000).

Recent Issues in Growth Curve Analysis

The prior developments in growth curve analysis represent an important but limited class of longitudinal data analyses (e.g., Nesselroade and Baltes, 1979; Bock, 1975; Pinherio and Bates, 2000). These developments have been distinguished by features of the models themselves: (1) the degree of mathematical specification, (2) the way these statistical models are fitted, and (3) the clarity and substantive meaning of the results. In future work, most of these problems are likely to remain under active investigation.

Most contemporary growth curve models can be written in a common symbolic form (Seber and Wild, 1989). A general model for a change in the scores over time (often using derivatives dy/dt or differences $\Delta y/\Delta t$) can be based on some mathematical functional form ($f\{x\}$) with unobserved scores ($x[t]$) and with unknown parameters ($\beta[t]$) to be estimated. Additional statistical forms not discussed here can be included, including autoregressive residual error structures, Markov chains, and Poisson processes. The growth functions described here are not an exhaustive listing and future extensions to more generalized functions, and to dynamic and chaotic forms are likely.

Recent research in statistical model fitting is important here too. It is now clear that growth curve models of arbitrary complexity can be fitted to the observed trajectory over time (i.e., the integral) and the unknown parameters can be estimated to minimize some statistical function (e.g., weighted least squares, maximum likelihood), and parameter estimates obtained using nonlinear programming. This generic statistical approach avoids some problems in older techniques, such as fitting a model to a log scale or directly to the velocity or the analysis of difference score data (**Figure 2**). These new techniques make it possible to address the critical problems of forecasting future observations, and further research on Bayesian estimation is the focus of current research here (for details, see Seber and Wild, 1989).

This generic model-fitting approach also permits a wide range of new possibilities for dealing directly with unbalanced, incomplete, or missing data. In early work, linear polynomials were used extensively to deal with these kinds of problems. But recent work on linear and nonlinear mixed and multilevel models have surfaced, making it possible to estimate growth curves and test hypotheses by collecting only small segments of data on each individual (Bryk and Raudenbush, 1992; Pinherio and Bates, 2000; Verbeke and Molenberghs, 2000; Preacher et al., 2006). These statistical models are being used in many longitudinal studies to deal with self-selection and subject attrition, multivariate changes in dynamic patterns of development, and the trade-offs between statistical power and costs

of person and variable sampling. The statistical power questions of the future are not 'how *many* occasions do we need?' but 'how *few* occasions are adequate?' and 'which persons should we measure at which occasions?' (McArdle and Woodcock, 1997; McArdle and Bell, 2000; Wu et al., 2009).

Some of the most difficult problems for future work on growth curves are related to the elusive meaning of the growth model parameters. Growth curve analyses also rely on basic measurement properties including (1) interval scaling, (2) age-and-time equivalence, and (3) substantively meaningful. These issues are key problems in the behavioral sciences and future research is needed to address these fundamental concerns. Multivariate models may be useful here, especially as these models are further extended to a fully dynamic time-dependent form. In any case, empirical information and experimentation will be needed to judge the utility of any growth curve model.

Given the long history of elegant formulations from mathematics and statistics in this area, it is somewhat humbling to note that many of the most insightful growth curve analyses have come from careful visual inspection of the growth curves (e.g., in **Figures 1–4**). The insight gained from visual inspection of a set of growth curves is not in dispute now and in fact obvious visual features should be highlighted and emphasized in future research (e.g., Pinherio and Bates, 2000). As in the past, the best future growth curve analyses are likely to be the ones we can see most clearly.

Growth Management and Urban Planning in the United States

Abstract

Growth management is a particular kind of comprehensive land use and facility planning used in parts of the United States to achieve a preferred form of the built and natural environment in a way that accommodates all projected growth. When done properly, growth management has been shown to elevate economic performance, raise the quality of life, reduce fiscal burdens, and improve environmental conditions relative to trend outcomes. This article defines growth management and its early history; outlines growth management's primary elements; differentiates growth management from related concepts; reviews growth management efforts at the state, regional, and local levels of government; and summarizes key benefits.

Growth Management Defined and Early History

Growth management involves projecting future development and land use needs and accommodating them so as to achieve goals relating to (1) preserving public goods, (2) maximizing positive land use interactions while minimizing negative ones, (3) minimizing fiscal burdens, (4) fairly distributing the benefits and burdens of growth and change, and (5) elevating the quality of life. It entails identifying appropriate locations for development to occur and to be steered away from. It also requires choreographing public facilities and their financing to achieve efficient land use patterns consistent with meeting growth management.

The Earliest Known Mention of a Growth Management-Like Effort Might Have Been Recorded in the Old Testament

> The Lord said to Moses … Command the people of Israel, that they give to the Levites … cities to dwell in; and pasture lands round about the cities … The pasture lands of the cities … shall reach from the wall of the city outward a thousand cubits all around. (Numbers 35: p. 1–4.)

This command is clearly aimed at containing urban development within a boundary so that farming can occur around it. Britain's 1947 Planning Act extended this concept by nationalizing greenbelt land and directing local government to contain urban development within stoplines.

The American experience is less draconian. The earliest growth management effort appears to have come out of Milford, Connecticut, in the early 1950s, which mapped high- and low-priority development areas. Development in low-priority areas needed to demonstrate that adequate public facilities existed to serve it without prematurely directing development away from existing urban areas. Moreover, approved projects could only be constructed in increments of 20% annually.

More famous is the plan devised by the Ramapo township, New York, in the mid-1960s. It provided for township build-out over an 18-year period. A capital improvements program helped to pace build-out during that period. Developers had to demonstrate that their project was consistent with the build-out plan (through a point system) and, if not, either wait for infrastructure to reach their site or install it themselves at their own cost.

A version of growth management, called 'growth control,' came from Petaluma, California, in the early 1970s, which capped development at 500 dwelling units annually. The cap was suballocated to different housing types to assure reasonable diversity of housing opportunities.

Generally, growth management aims to influence the location, magnitude, and timing of urban development through land use and capital facility planning, and development permitting. Unlike conventional planning whereby land is designated for particular land uses and facilities are extended when market demand dictates, growth management is a more conscious effort to shape development patterns during discrete intervals of time based on explicit urban form objectives.

Primary Elements

Growth management planning is composed of six elements: (1) establishing a vision for the desired form of land use patterns that meets growth management goals; (2) guiding growth toward achieving that vision; (3) using infrastructure to facilitate the desired development patterns; (4) preserving open spaces from development; (5) enhancing community quality of life by improving accessibility to jobs, services, shopping, and other destinations as well as providing stable housing markets and neighborhoods, among other things; and (6) coordinating actions between different government units to achieve the overall vision. Each of these elements is summarized in the following discussion.

Overall Form: Creating the Vision

A first step in the growth management planning process is projecting population, housing, employment, and nonresidential space needs in a horizon year (often 20 years out but it could be more or less), and comparing them to existing conditions to determine net new development needs. This is followed by identifying alternative development scenarios to meet those needs. Typical scenarios include development based on historic patterns, which in the United States is typically the perpetuation of low-density urban sprawl where land

uses are disconnected and the single-occupant vehicle is the principle if not the only mode option; development based on accommodating all future development on existing urbanized land, which usually means relying on infill and redevelopment to meet future land use needs; and one or two scenarios in between. Each scenario is compared along numerous dimensions determined by the scenario planning leaders but often includes housing mix and affordability, jobs-to-housing balance, infrastructure needs and their costs, amount of open space consumed, air and water impacts, and transportation modes needed to connect land uses within each scenario.

Often, the outcome of a visioning process is the conclusion that more compact, integrated development patterns served by multiple transportation modes consume less land (thereby preserving more open space), provide important economies in infrastructure delivery, create synergies between land uses, enhance residential choice, reduce vehicle miles traveled per person, reduce air pollution and water consumption, and have other benefits compared to more sprawling, disconnected land use patterns with fewer transportation mode options. To maximize total benefits, the preferred scenario usually includes urban growth boundaries, British-style development stoplines, or urban service limits. They are called collectively 'urban containment boundaries' (UCBs) and are complemented by urban service plans that control the location, size, and timing of infrastructure improvements. Land within the UCB may be subdivided into different categories for the phasing of services, depending on development suitability, proximity to existing public facilities, contiguity with existing development, and other factors. Sufficient land must be included within a UCB to accommodate market demand within the planning horizon. If too little land is included, land prices may increase beyond the ability of the market to accommodate development needs. Too much land defeats the purposes of encouraging compact, contiguous development and usually results in excessive and premature capital outlays for public services.

Growth Guidance

Growth guidance relates to the timing, phasing, and dimensioning of development within UCBs. Within UCBs, there may be intermediate containment boundaries which, as their name suggests, are short-term development boundaries within the long-term UCB. In contrast, outside UCBs, there may be urban development reserves where future urban development will be targeted once the UCB is filled in.

Growth management usually results in 'upzoning' land within UCBs and 'downzoning' land outside. The reason is simple. Land intended for urban development should accommodate more intense activity and land not intended for urban development should be prevented from urban development.

The 'upzoning/downzoning' requirement permeates through other land use policies. For example, conventional planning uses transitional zoning to buffer land use activities from each other and to facilitate a concentric ring urban form wherein uses farther away are at lower densities than those closer in. Transitional zoning is not generally compatible with growth management, however. The result of transitional zoning is that low-density and very low density land uses expand into rural areas and into resource lands, thereby perpetuating urban sprawl and undermining the long-term economic viability of resource production. Instead, growth management programs use mixed use, nontransitional zoning strategies, which, among other things (1) establish moderate- to high-density and moderate- to high-intensity land use categories throughout much of the urban area, (2) direct infill and redevelopment into urban and suburban commercial areas, (3) where they exist, steer development into transit development-oriented areas, (4) reduce the scale of low and very low urban densities within urban areas, (5) eliminate low-density and very low density development in areas that are predominantly resource lands or other environmentally sensitive lands, and (6) restrict the size and location of low-density and very low density development outside UCBs and away from resource or environmentally sensitive lands.

Growth management also aims to eliminate exclusivity. Many communities use zoning strategies to exclude certain classes of people, especially those occupying low-income housing. A typical strategy is to zone the community for large lot sizes and large minimum floor areas. Low-income households will thus be unable to afford to live in the community. Growth management recognizes the need to provide housing to all income levels. Many growth management communities have 'inclusionary zoning' policies that require large-scale projects to have housing opportunities affordable to a wide range of households.

Finally, it is one thing to designate land for moderate- to high-density development and give developers the impression that they have flexibility in meeting market demands but it is quite another to actually allow such densities. Unwary developers who propose high-density developments can get stalled in decision making, often because existing residents oppose such developments. Housing density is usually reduced but this defeats the purpose of growth management. The solution is 'minimum density zoning.' Miami-Dade County, for instance, requires communities to achieve an average of at least 75% of the maximum allowable density for residential zoning categories over near-term planning periods. If a community has a zoning category that allows up to 10 units per acre, the average of new projects built in that category can be no less than 7.5 units per acre.

Infrastructure Provision

Growth management cannot succeed without infrastructure planning and financing that makes urban development more attractive than development in the countryside. On the other hand, development must not exceed the ability of existing infrastructure to accommodate it. 'Adequate public facility' standards assure that, in addition to meeting applicable zoning and subdivision standards, facilities and services are able to serve it. 'Concurrency,' whereby facilities needed to serve new development are in place or committed concurrent with the impacts of new development, is another version of the same principle.

Under growth management, infrastructure is often a shared responsibility between government and developers. One form of share responsibility is 'development exactions' in which the developer provides a certain range of infrastructure

at her or his cost. Infrastructure within the development is normally the developer's responsibility but the responsibility for financing offsite roads, water, sewer, schools, parks, and other facilities is complex. Offsite infrastructure costs are often financed through ad hoc exactions or impact fees – or sometimes a combination. Ad hoc exactions are concessions made by the developer to local government to mitigate the impact of development. Traffic lights and water and sewer extensions are examples. Impact fee are one-time assessments on new development and to pay for new or expanded facilities needed to serve new development, help cover a share of the offsite costs. The fees are calibrated to cover the costs of one or more specific facilities apportioned to the development, such as parks or roads.

Protecting Open Spaces

What happens outside UCBs? Growth management is not effective unless it preserves open spaces and manages rural density development. Some states, such as Hawaii and Oregon, are very aggressive in preventing any development of open spaces. In these states, 'exclusive farm/forest use' regulations require owners of such land to manage it for farming and forestry if they wish to live on it.

Economic mechanisms can be used to encourage development inside UCBs and prevent development outside. 'Purchase of Development Rights' programs involve public acquisition of the development rights of open spaces. 'Transfer of Development Rights' programs involve developers acquiring development rights from open space owners in rural areas for transfer to areas within UCBs at higher density.

Not all land outside UCBs is appropriate for farming, forestry, or other open space uses. Indeed, there is some demand for rural living that if not accommodated would result in urban households acquiring farms and then maintaining only the yard they wish, typically one-quarter to one-half acre. 'Clustered' development in rural areas is one solution. For example, a 100-acre farm may be subdivided into 10 parcels of which nine are 1 acre and one is 91 acres, which in many parts of the country is sufficiently large to accommodate reasonable commercial farming operations.

Enhancing Community Life

Growth management changes existing neighborhoods. Oddly, many neighborhoods view growth management as anathema to their quality of life especially if infill and redevelopment activities locate there. 'Design review processes' help assure that new development in stable neighborhoods enhances neighborhood character. 'Supplemental housing' such as mother-in-law, overgarage, basement, or attic living units allowed in established neighborhoods improve property values, increase safety (more 'eyes-on-the-street'), make more efficient use of infrastructure, and generally assure neighborhood stability thereby increasing neighborhood vitality.

Coordination between Governments

Growth management is not effective in isolation. Because a number of governmental units interact with each other, effective growth management needs all relevant governmental units to share the same vision for a preferred built and natural environment. Intergovernmental coordination is necessary. 'Cross-acceptance is one way in which this is achieved.' Conceptually, this means that all units of government affecting a particular community – including state, regional, local, and special district governments (such as school districts, water districts, fire protection districts, and the like) – agree to each other's plans and they all agree to share the vision of the region's future built and natural environment. 'Extraterritorial jurisdiction' allows municipalities to decide on the efficacy of development proposed outside its jurisdiction within some distance, usually the equivalent of 5–10 km. 'Annexation policies' enable municipalities to assure that development outside their boundaries meet certain minimum requirements prior to annexation.

'Tax-base sharing' removes the incentive of individual local governments to offer lucrative incentives to particular kinds of development that may offer unique property tax or sales tax benefits. A shopping center locating in one community would have a portion of its property and sales tax revenue shared with nearby communities. This removes competition between communities for tax base, thereby preventing costly concessions by host communities and compensating all affected communities for potential impacts.

Growth Management Differentiated from Related Concepts

Growth management is not to be confused with growth controls (also known as 'development control' in the United Kingdom), sustainability, or smart growth, although some elements may be common across all three. Growth management focuses on accommodating anticipated growth in efficient and equitable land use arranges. Growth control, in contrast, reduces the amount of growth that is allowed. This can lead to exclusionary outcomes where only affluent households can afford to live in growth-controlled communities. On the other hand, natural constraints may require growth restrictions such as is found in the Florida Keys, Sanibel Island, Rocky Mountain resort towns, and elsewhere. Even in these situations, growth control plans often include efforts to meet development needs elsewhere proactively, such as affordable housing requirements imposed on all new development in several Rocky Mountain resort towns.

At its heart, sustainability is about making decisions today that do not foreclose options for future generations. While it can address social and economic concerns, it is mostly an environmental and ecological approach to planning. One could argue that all land use planning approaches including growth management are a subset of sustainability but there is no consensus.

In recent years, 'smart growth' has emerged as the popular characterization of what growth management tries to accomplish. There is a certain appeal to avoiding the term 'growth management' as it connotes controlling growth, which it does not, while the term 'smart growth' implies that doing otherwise would result in 'dumb' growth. Yet, smart growth has no

overall goals, while growth management does. Its goals include protecting public goods, minimizing taxpayer costs and maximizing long-term economic benefits, minimizing adverse and maximizing positive land use interactions, equitably distributing the benefits and burdens of development, and elevate the quality of life.

State, Regional, and Local Applications

Examples of growth management at different levels of government are reviewed here.

State Growth Management

Only a few American states engage in growth management on a statewide level. Five are summarized here: Hawaii, Oregon, Washington, Maryland, and Florida.

Hawaii, the nation's newest state, has the nation's oldest statewide growth management and for good reason: it is composed of islands for which there are very few alternatives to sharing development needs with agricultural and environmental needs. Through efforts by a state planning agency pursuant to the Hawaiian Land Use Law of 1961, all land on major islands is designated for urban, agriculture, low-density rural, and conservation land uses. Counties (individual islands) have very little say about those allocations.

The state with the longest history of statewide growth management among the contiguous 48 states is Oregon. The Land Conservation and Development Act of 1973 established a state commission and an administrative department. Like Hawaii, land in the state is designated essentially for urban, agriculture/forestry, low-density rural, and conservation uses. Unlike Hawaii, local governments have a significant say in how those allocations are made. Today, Oregon's land use pattern is a system of urban centers contained within UGBs surrounded by open space.

Oregon's program has four important features that are not found in other growth management states. First, it requires all local governments to project and then accommodate future development needs. Although other states also require projections, Oregon is the only one that requires local governments to actually designate land (through zoning) targeted to accommodate development needs; this reduces the opportunity for opposition in the future to thwart the kind of development that is needed to accommodate development needs.

Second, Oregon requires clear and objective review standards. Such vague review terms as 'minimizes drainage' are replaced with engineering standards that are clearly understandable by developers. Those standards must also be 'reasonable.'

Third, Oregon sets a time limit for reviewing development proposals that are 'quasijudicial' in nature (i.e., not requiring policy making such as a plan amendment). Local governments have 120 days from the time the proposal is formally and completely submitted to make a decision to approve, deny, or approve the proposal with conditions. If the 120-day limit is missed, the development can be granted automatic approval by a local judge. (Not a few local planners have lost their jobs by missing this deadline.)

Last, Oregon is unique in the United States in having a Land Use Board of Appeals (LUBA) that decides land use appeals at the state level. Appeals are to be decided within 120 days of filing. Moreover, appeals from LUBA's decisions must be decided by the Oregon Court of Appeal within 120 days of LUBA's decision. In all, under Oregon law, nonlegislative land use decisions must be decided within about a year. In contrast, court systems in other states can take years and sometimes decades to decide.

In the early 1990s, the state of Washington adopted its Growth Management Act (GMA), which has many of the same features as Oregon, including UGBs and open space preservation. Key differences are that the law applies only to counties meeting certain urban criteria and others that wish to voluntarily come under the GMA. Another difference is that it does not go as far as Oregon in requiring local governments to designate land to accommodate development needs. And, although it has an appeal process, it is through a system of Growth Management Hearing Boards at the county level.

Florida's growth management efforts, stemming from the 1970s and revamped in the mid-1980s, are relatively weak in containing urban development or preserving open space from low-density rural development. Its 'concurrency' provisions, however, which limit new development to only those areas where adequate public facilities exist or are planned, appear to have shifted development away from many open spaces to infill and redevelopment sites. But the Florida approach does not appear to have managed development overall in recent years.

A cornerstone of Florida's effort is the separation of urban and rural land uses. This is seen as a principal way in which to prevent urban sprawl. To accomplish this, local governments have used UGBs, urban service limits, phased urban extension planning, and open space preservation.

As initially conceived in the mid-1980s, a state–local partnership would use various state and local tools to match housing supply with demand to avoid overproduction that led the state into recessions historically. For a while, the GMA worked. In 1990, before the GMA took hold fully, the statewide housing vacancy rate stood at 15.3%, while the median home value to median household income ratio was 2.9. In 2000, a decade into the GMA, the vacancy rate dropped to 12.8%, while the home value to income ratio dropped to 2.7. But the 2000s saw a succession of Republican governors dismantle the state–local partnership allowing local governments to approve developments far in excess of demand. By 2010, Florida's vacancy rate shot up to 17.4%, the home value to income ratio rose to 3.0, and Florida led the nation in foreclosures. Overproduction of housing once again led Florida's economy into recession.

Maryland's growth management initiative was launched in 1997 through the Smart Growth and Neighborhood Conservation Act. Its goals include enhancing existing communities and other locally designated growth areas, protect valuable farmland and other natural landscapes, and reduce the cost of infrastructure. The state's Smart Growth Program finances infrastructure projects in designated Priority Funding Areas and provides inducements to protect landscapes outside those areas. It was the first state to explicitly use state funds to direct growth into targeted areas. Assessments indicate that since the

middle 2000s, the effort has increased the statewide share of development occurring in Priority Funding Areas and reduced the share of development outside them.

Regional Growth Management

In this context, regions can include multiple counties or large counties with multiple cities within them. Three efforts are highlighted: the Twin Cities Metropolitan Council serving the Minneapolis-St Paul metropolitan area, the New Jersey Pinelands Commission; and the Baltimore County, Maryland.

One of the earliest and best known regional growth management efforts is that of the seven-county Twin Cities (Minneapolis-St Paul) metropolitan area established by state law in 1967. This example of regional growth management was accelerated through another state law in 1976 that led to a four-step regional planning process. First, Twin Cities Metro Council staff would project future growth demands for housing, employment, and other land uses. Second, vacant land that was already 'serviced' with sewers and roads was identified along with land having environmental constraints; this led to an inventory of land available for development. Third, the Metropolitan Urban Service Area (MUSA) plan required to provide enough land within each subarea of the region to accommodate realistic growth needs over the next 10 years while minimizing the public infrastructure investments. The last step was to present alternative density scenarios for the MUSA along with estimates of public investments needed to implement each. A planning process would then adopt one scenario or a hybrid to guide development. Once the 10-year scenario is adopted and implemented, it is reviewed every 5 years to make adjustments as needed.

The New Jersey Pinelands is another example of regional growth management. The Pinelands Comprehensive Management Plan manages development to preserve the area's unique natural, ecological, agricultural, archeological, historical, scenic, cultural, and recreational resources. The effort is managed jointly by the state of New Jersey and the US Department of the Interior through the New Jersey Pinelands Commission whose jurisdiction includes parts of seven counties.

A cornerstone of the plan is the combination of urban containment and transfer of development rights. Landowners in preservation areas are granted a certain number of development 'credits' that they can sell to developers to use in 'regional growth areas.' Once sold, landowners within preservation areas are subject to conservation easements, restricting them to nonresidential uses only. Developers may use each acquired credit to build four more residential units than otherwise allowed by the local zoning code. The program has protected more than 12 000 acres of sensitive land while directing development to targeted regional growth areas.

In 1967, Baltimore County, Maryland, created its 'urban–rural demarcation line' for the purpose of preventing urban development in the county's rural areas. Tools used to protect rural land from urbanization include agricultural districts, a land trust established under the state's Rural Legacy program, development clustering, property tax incentives for conservation, and acquisition of conservation easements. The growth management plan is implemented by seven major local governments including Baltimore city. A *de facto* UGB is administered by the Metropolitan District of Baltimore County, the county's public sewerage agency, through its sewer service area boundary. This does not prevent large-lot subdivisions using onsite sewerage treatment facilities ('septic systems') from encroaching into rural areas, however.

Local Growth Management

Every state has at least one example of local government efforts. Three very different ones are reviewed here: Sioux Falls, South Dakota; Boulder, Colorado; and Lincoln–Lancaster County, Nebraska.

Sioux Falls' initial growth management policy was adopted in 1979. It was an outcome of poor planning combined with development pressures that threatened the Big Sioux River with pollution from failing septic systems. The outcome was a set of public facility policies that limited development both inside and outside the city limits to sewer systems. To manage the outward expansion of development, a plan was crafted for seven districts. Within each district, the plan notes the timing and extent of investment in future urban infrastructure. Thus, by phasing infrastructure extensions, the city manages the timing and pattern of future growth. Land outside the urban area is subject to agricultural zoning that minimizes rural residential development.

Boulder, Colorado, has one of the United States' longest histories of growth management, dating to 1958 when the city limited water extensions above 5750 ft. This was to protect the Rocky Mountain foothills viewshed for Boulder residents. In 1967, the city became the nation's first to purchase open space for viewshed protection purposes; it was financed in part through an increment to the local option sales tax. In 1976, voters approved the Growth Limitation Ordinance, which controlled growth through capital facilities planning within an UGB. To prevent development from outflanking the Boulder UGB, there is an intergovernmental agreement with Boulder County to restrict land uses outside the UGB to rural, mostly residential and open space, uses for several miles around it.

In 1994, the city of Lincoln and Lancaster County, Nebraska, adopted a comprehensive plan restricting the extension of water and sewer services outside the city limits. The plan includes an assessment of existing and future infrastructure needs over a 20-year planning period. The city then manages the location and timing of future growth through its infrastructure extension policies. Once served, new development is annexed in to the city. Moreover, the state of Nebraska provides Lincoln with extraterritorial zoning authority over land within 3 miles of its boundaries. This allows the city to prevent premature annexation of urban-scale development that occurs outside its boundaries. The intergovernmental agreements combined with state-granted powers provide Lincoln with the ability to manage growth through the planned extension of its infrastructure and subsequent annexation.

Benefits

For a long time, the benefits of growth management in the United States seemed illusory. Evidence is emerging that when

growth management plans include policies composed of the overall growth management goals noted above, important benefits result. They include more housing choices and higher supplies of affordable housing, more transportation options, more open space preservation combined with larger supplies of 'working' landscapes (such as farms and forests), more jobs resulting in lower unemployment and higher wages, more economic opportunities for minorities, lower public facility costs, and greater fiscal capacity principally because economics are more efficient and resilient.

Abstract

In US criminal law, a person is guilty of a crime when a court of law determines beyond a reasonable doubt that they have violated a criminal law or performed acts that meet the elements of a criminal offense that is established through statute. The determination of guilt through criminal law reflects the expectation of society that individuals should be held accountable for their judgments and actions resulting from their exercise of free will. This article defines the concept of guilt in US criminal law and explores how criminal cases arrive at a guilty verdict. Additionally, the article examines errors of guilt and the meaning of an acquittal from guilt.

Definition of Guilt

A crime is an intentional act that is committed without excuse or justification. The act has been determined by the state to cause harm that results in punishment through criminal prosecution. A person is determined to be guilty of a crime when a court of law finds beyond a reasonable doubt that person has violated a criminal law or performed acts that meet the elements of a criminal offense that is established through statute.

The determination of guilt through criminal law reflects the expectation of society that individuals have free will and should be held accountable for their judgments and actions resulting from the exercise of that will. Law in the United States was heavily influenced by English common law (judge-made law). One of the most important principles of common law is the notion that crimes require both *actus reas* or a 'voluntary and guilty act' and *mens rea* or a 'guilty mind' to occur simultaneously. As a result, the state must prove that a person voluntarily engaged in behavior that constitutes a criminal act and had the intent to violate the law. There is no crime without a bad act, although failure to act or do something required by law may also constitute a crime. For example, parents have a legal duty to protect their children from harm and failure to do so may constitute a crime of neglect.

To be found guilty of a crime, the state must prove beyond a reasonable doubt that a person who committed a criminal act intended to commit a crime. Intent can be general or specific and the legal standards to prove intent differ from crime to crime. For example, to be guilty of a crime of murder, a person must demonstrate a state of mind to do harm (malice) before the commission of a homicide. Homicide without 'malice aforethought' is manslaughter not murder. There are some situations where people who commit criminal acts cannot form the intent necessary to be found guilty of a crime. In William Blackstone's *Commentaries on the Laws of England* (1790), he suggests children under the age of seven are 'conclusively presumed' not to be able to form criminal intent. Between the ages of 7 and 14, children are presumed not to be able to form the intent to commit a crime but that presumption can be refuted through the presentation of evidence. Common law has historically presumed that children who were 14 years and older were responsible for criminal acts. In the United States, state laws have increased or decreased the age of criminal responsibility overtime. All states now have juvenile courts where criminal conduct of minors is addressed through juvenile rather than criminal proceedings. Juveniles are adjudicated as delinquent as opposed to being adjudicated as guilty. Blackstone (1790) also argued that the insane cannot form the intent necessary to commit a criminal act.

Criminal acts can also be justified. In certain circumstances, the law also excuses people from crimes committed in defense of themselves, other people, or property. A defendant who claims self-defense must prove that he or she did not provoke the threatening events, faced an immediate threat to which there was no other way to escape harm and genuinely believed that there was no alternative to the use of force. Since 2005, 18 states and the federal government have adopted 'stand your ground' provision within their criminal law, allowing a person to defend themselves, others, or their property without the requirement to retreat to safety (McClellan and Tekin, 2012) (these states include Alabama, Arizona, Florida, Georgia, Indiana, Kansas, Kentucky, Louisiana, Michigan, Mississippi, Montana, New Hampshire, Oklahoma, South Carolina, South Dakota, Tennessee, Texas, and West Virginia). Those acting under duress or being compelled by another to engage in criminal acts that he or she would otherwise not commit may also be excused from guilt.

If a person is charged with a violation of a criminal offense, either through indictment by grand jury or through a prosecutor filing an information, their case can be disposed of in three main ways. First, person can plead guilty to the offenses charged or bargain with the prosecutor to plead guilty to a lesser charge and have the disposition of their sentence be determined by a judge. In some US jurisdictions, a person accused of a crime has the option of pleading *nolo contendere*, which essentially means the defendant does not affirm or deny the charges. Courts must consent to accept a *nolo contendere* plea. The effect of the plea is similar to a guilty plea in that once the plea is rendered a judge determines the appropriate sentence. Second, a person can plead not guilty to the formal charge and elect to have a judge or a jury of their peers hear evidence and determine their guilt through a criminal trial, the result of which could be a finding of guilt, an acquittal, or a hung jury. Third,

a prosecutor can elect to dismiss charges against a person before a plea of guilt or a court of law determines guilt through trial.

To be found guilty of a crime by jury trial or trial before a judge without a jury, the prosecution must present evidence proving beyond a reasonable doubt that the defendant committed the accused criminal act. The prosecution must establish that all elements of the crime that are required by law occurred in the alleged offense and present evidence of the defendant's intentional misconduct and blameworthiness.

Patterns of Guilt

The trial by jury or judge in states where a defendant has the right to waive a jury trial is the judicial process that determines a person's guilt or innocence. Until the early twenty-first century, most criminal cases in the US were disposed of through trial. Today, however, the typical outcome of a criminal case is a conviction based upon the defendant's entry of a guilty plea.

Prior to the early part of the twentieth century, criminal trials were conducted swiftly and most defendants elected to have their cases heard before a judge or jury (Alschuler, 1979; Friedman, 1979). Courts often resolved multiple criminal trails in a single day because cases were commonly not complex and there were fewer procedural rules or rules of evidence. Defendants often did not have lawyers acting upon their defense. The professionalization of the criminal justice system in the form of state prosecutors and professional police meant screening of criminal offenders shifted from primarily the responsibility of judges and juries to police and prosecutors. The rising authority and autonomy of police and prosecutors corresponded with widespread corruption among criminal justice officials in the early twenty-first century. Anecdotal evidence from this time also suggests some prosecutors were willing to make concessions to criminal defendants to reduce charges in exchange for fees (Alschuler, 1979). By the 1920s, criminal caseloads in major US cities had increased significantly and a majority of cases were resolved through plea bargains since cases could be processed relatively quickly and efficiently (Alschuler, 1968). In 1971, the US Supreme Court upheld the constitutionality of plea bargaining in Santobello v. New York (404 U.S. 257).

State Courts

Of criminal cases disposed in the largest urban counties in the United States in 2006, the year of most recent available statistics (see Table 1), 68% of the individuals charged with felony offenses were actually convicted of felony or misdemeanor crimes. Of those who were convicted, the overwhelming majority (approximately 96%) pled guilty. Prosecutors decided to dismiss cases before adjudication in another 23% of all cases. Eight percent of all cases were either disposed through alternatives to traditional criminal punishment or resolved in the following year. Acquittals accounted for only 1% of all case outcomes. This pattern has been very consistent over time.

According to the Bureau of Justice Statistics data, only 3% of all criminal cases were actually resolved through trials in which judges or juries rendered verdicts of guilt or acquittal. While acquittals represent only a tiny fraction of all criminal dispositions, they make up a much larger proportion of those cases that do go to trial. Approximately one third of all criminal cases resolved through trial result in the acquittal of the defendant.

Federal Courts

The dominance of plea bargaining as the primary method of disposing of criminal cases is even more evident in the federal criminal justice system. Of the 98 489 defendants in cases that were closed by federal prosecutors in 2010, an astonishing 92% were convicted (Bureau of Justice Statistics, 2013). Just under 8% of defendants had their cases dismissed by prosecutors or were given pretrial diversion. Less than 1% of all federal defendants were acquitted by either federal juries or federal judges. In the federal criminal justice system, the guilt is determined predominately by the prosecutor. Highly structured federal sentencing laws have limited judicial discretion and incentivized defendants accepting responsibility through a guilty plea and cooperating with the government as a mechanism to reduce tough sentences (Etienne, 2003). Of the federal defendants whose cases were prosecuted to conclusion (i.e., they were not dismissed or resolved through pretrial diversion), 97% plead guilty as the result of a plea bargain. The proportion of cases resulting in a plea bargain has risen substantially since 1990 when only 80% of federal cases prosecuted to conclusion resulted in a guilty plea (Brown et al., 1984).

Table 1 Adjudication outcomes for felony defendants in large urban counties (2006)

			Convicted of felonies			*Convicted of misdemeanors*			*Not convicted*		
Most serious arrest charge	*No. of defendants*	*% Convicted*	*Total*	*% Plea*	*% Trial*	*Total*	*% Plea*	*% Trial*	*% Dismissed*	*% Acquitted*	*% Other outcome*[a]

Mistakes of Guilt

The US criminal justice system has a two-stage process for determining who is guilty of a crime following arrest. In the first stage, prosecutors screen criminal cases to eliminate those cases where there is insufficient evidence to prove a person's guilt. Prosecutors must either present information to a grand jury that there is a probable cause to believe a defendant committed a crime sufficient to warrant a trial or file an information, a document presenting evidence of a defendant's commission of a crime. Even after charges are filed, prosecutors regularly assess the strength of their case against a defendant. In advance of trial, they may discover that key witnesses will not agree to testify or evidence-supporting prosecution is weaker than they originally believed. Prosecutors may decide to dismiss a case because they do not think they can convince a jury of the defendant's guilt and the defendant cannot be persuaded to plead guilty. Prosecutors have significant and unreviewable discretion to pursue or dismiss criminal charges and are commonly considered the "gateway to the criminal justice system" (Kerstetter, 1990: p. 268). In the second stage, courts adjudicate guilt in the hope that judge or jury fact finders will prevent falsely accused defendants from being unjustly convicted of a crime. The US criminal justice system is designed to err on the side of acquitting the guilty. At trial, juries are informed that defendants are to be presumed innocent and it is the burden of the government to prove defendant guilt beyond a reasonable doubt.

Any fear about innocent defendants being erroneously convicted is alleviated by a widespread belief that innocent people have been effectively screened out before criminal charges are filed (Givelber, 2005). As Edwin Meese III, United States Attorney General under President Ronald Reagan, once explained, "… you don't have many suspects who are innocent of a crime. That's contradictory. If a person is innocent of crime, then he is not a suspect" (Justice Under Reagan, 1985). As a result, errors in the adjudicatory process should only result in the acquittal of the guilty. But mistakes do happen.

While the true extent of wrongful convictions is unknown, since DNA evidence was first used to help exonerate defendants from erroneous convictions in 1989 (DNA evidence was first used in 1989 to exonerate Gary Dotson who was wrongfully convicted of rape and incarcerated in Illinois for 10 years), the courts have increasingly used new forensic methods to establish innocence. Analyzing hundreds of exonerations occurring since the late 1980s, Gross et al. (2005) estimated the number of mistaken convictions to "be in the thousands, perhaps the tens of thousands" (551). To date, just over 300 people have been exonerated postconviction through forensic evidence that established their innocence (Innocence Project, 2013). Landmark research conducted by Bedau and Radelet (2004) analyzing hundreds of cases of wrongful convictions occurring in capital cases suggests that mistakes of guilt happen even in the most serious cases.

Wrongful convictions occur for a number of different reasons. Eyewitnesses misidentify suspects (Garrett, 2011), informants provide false statements to prosecutors and perjure themselves during testimony, and prosecutors make errors (Gross and Shaffer, 2012). Defendants may also be persuaded to falsely confess to crimes they did not commit, usually under psychological coercion by the police (Ofshe and Leo, 1997). Defendants provided false confessions in nearly two-thirds of the homicide cases exonerated by DNA evidence (White, 2003). Often defendants confess to crimes they did not commit and agree to accept a plea bargain because they do not understand the evidence against them. When a defendant agrees to accept a plea bargain he or she gives up the right to see evidence from the prosecution that may support his or her claim of innocence. As a result, people may plead guilty to a crime even when the state has evidence that indicates their innocence.

It is nearly impossible for a defendant to establish their innocence once they have been convicted of a crime. On appeal, the defendant must persuade the court that no reasonable judge or jurors could have concluded that they were guilty of the accused crime (House v. Bell, 2006).

The Meaning of an Acquittal

A person who is legally acquitted of a crime has claimed innocence of the criminal charge and had their case heard at trial. The finding of 'not guilty' by a judge or jury reflects that the state has failed to provide evidence sufficient to establish the defendant's guilt beyond a reasonable doubt. It is possible that the state was correct that the defendant committed the crime but simply failed to persuade a judge or a jury that this was the case. The criminal justice system is replete with examples of guilty people who were erroneously acquitted. In these cases, the prosecutors or the police produce evidence such as confessions or statements by codefendants that could not be presented to the jury due to due process considerations. To ensure adherence to the mandates of the Fourth Amendment to the United States Constitution prohibits unlawful searches and seizures, the Supreme Court has determined that evidence seized in violation of these provisions cannot be presented to judges or juries to determine a defendants' guilt (Weeks v. U.S., 1914; Mapp v. Ohio, 1961). Interviews with jurors following a not guilty verdict also demonstrate mistakes jurors made in applying the law. Double jeopardy prevents the state from appealing acquittals, so there are no appellate court rulings clarifying when an acquittal is appropriate. The legal inquiry ends when the jury or judge returns a not guilty verdict.

Actual innocence is nearly impossible to prove. While guilt rests upon a conclusion about the defendant's behavior, an acquittal reflects only an absence of proof or a finding that guilt should be set aside due to legal error. Judges or juries do not address the question of whether or not a defendant is truly innocent. Once they decide that the prosecutor has not made a persuasive case that the defendant is guilty their work is done. Actual innocence is a question that judges and juries are neither asked nor expected to answer. Claims of actual innocence require judgments beyond those that are made by criminal courts.

Absent definitive answers about whether or not people who are acquitted of crimes are actually guilty, empirical research has examined the degree to which acquittals correspond to factors that are consistent with actual innocence. Kalven and Zeisel's (1966) seminal research in *The American Jury* relied on surveys from hundreds of judges to determine the accuracy

of jury verdicts. They found that judges agreed with the jury verdicts in the majority of cases. When judges and juries disagreed, juries were more likely to acquit when judges would have convicted (19% of all cases) than they were to convict when the judges would have acquitted (3% of all cases). Kalven and Zeisel (1966) sought to explain why juries acquitted when judges would have convicted suggesting that in cases that were close on the evidence juries were 'liberated' to consider non-evidentiary factors such as personal and community values in deciding to acquit a defendant whom the judge would have convicted. For the past 50 years, the 'liberation hypothesis' has the dominant theory to explain acquittals. New research looking at data on jury decision making in four US cities, challenges this perspective. Using survey data from both judges and juries, Givelber and Farrell (2012) find that jury acquittals actually reflect the evidence presented at trial. Juries acquit in the face of unpersuasive presentations of evidence by the prosecution, more persuasive presentations of evidence by the defense, or both. Despite the best efforts of prosecutors to screen for guilt, the jury does its job when the innocent are prosecuted and acquitted and fails in its task when the innocent are prosecuted and erroneously convicted.

Guns and Criminals

Abstract

The first systematic effort to understand where, how, and why criminals acquire, carry, and use guns was by Wright and Rossi (1986). Key findings were that criminals rarely acquired firearms through conventional retail markets, that much criminal gun possession was self-defensive and not specifically for the purpose of committing crimes, and that criminals were for various reasons adept at finding ways to circumvent stricter gun controls. This article reviews subsequent research on these and a range of related topics.

In 1986, Wright and Rossi published *Armed and Considered Dangerous: A Survey of Felons and Their Firearms* (ACD), the most comprehensive survey and analysis then available (or since) of where, how, and why criminals acquire, carry, and use guns. A second edition was published in 1994 and a third in 2008; in both cases, there were new prefaces pointing out that the main themes and findings had held up remarkably well in the face of new research and evidence. Despite its advanced age, "no research has satisfactorily disentangled" the effects of gun acquisition any better than the 1986 study (Hauser and Kleck, 2013). But what of even newer research on gun-related topics? The purpose of the present article is to review the literature pertaining to the criminal acquisition and use of firearms produced in the years since ACD was initially published, with an emphasis on the post-2008 literature.

The Criminal Gun Market

Major replications of ACD's findings concerning firearms acquisitions by imprisoned offenders were carried out in the Surveys of Inmates in State and Federal Correctional Facilities (SISCF and SIFCF) in 2004. The 2004 SISCF was conducted for The Bureau of Justice Statistics (BJS) by the US Census Bureau, which also conducted the SIFCF for the Federal Bureau of Prisons (BJS, 2004). Both surveys include information about current offense and criminal history; family background; personal characteristics; prior drug and alcohol treatment; gun possession; and prison treatment, programs, and services. Unlike the ACD survey, which sampled only male inmates in state prisons, the BJS studies added federal prisoners to the sampling frame and sampled both male and female inmates. The sample sizes were also an order of magnitude larger (about 2000 in ACD vs about 18 000 in the BJS surveys). A final important difference is that the ACD questionnaire was largely self-administered, whereas the BJS surveys utilized computer-assisted personal interviews.

Methodological differences aside, the findings from the 2004 BJS surveys are very similar to those reported in ACD. The BJS surveys found that approximately 16% of state prison inmates and 18% of federal prison inmates who used, carried, or possessed a firearm when they committed the crime they were currently serving a sentence. During the offense that landed them in prison, only 2–3% carried a military-style weapon. The criminal preference for conventional handguns, which compromised 13–16% of the firearm possessions, over the so-called 'assault weapons' was again confirmed.

Perhaps the most commonly cited finding from ACD was that criminals rarely obtained guns through conventional retail channels. (Thus, by implication, controls imposed at the point of retail sale largely miss the majority of criminal firearms transactions.) In the 2004 survey of state inmates, among those who possessed a gun at the time of their arrest, "fewer than 2% bought their firearm at a flea market or gun show, about 10% from a retail store or pawnshop, 37% obtained it from family or friends, and another 40% obtained it from an illegal source" (BJS, 2004: 13). This closely resembles the findings in ACD (p. 185) that "one out of six of the men in this sample acquired his most recent handgun through means and sources likely to be concerned about the legality of the transaction; five out of six did not." ACD showed and subsequent studies have confirmed that "the illicit firearms market … [is]…clearly and heavily dominated by informal, off-the-record transactions, either with family and friends or with various gray- and black-market sources" (p. 190).

The BJS findings are of particular interest because in the decades since ACD was published, much legislation and commentary has focused on 'military-style assault weapons' and on the illegal acquisition of firearms at gun shows and flea markets. Recently, Dan Gross (President of the Brady Campaign to Prevent Gun Violence) stated, "most Americans would be outraged to learn the number of loopholes that allow felons and other dangerous people to get their hands on machine guns and other military-grade firearms" (2013). This campaign, as well as both houses of Congress, has lobbied and passed legislation attempting to control firearm sales at gun shows. One legislator claimed, "70 percent of guns used in crimes come from gun shows" (Kopel, 2000). However, no study, and certainly none with any sort of methodological credibility, has ever found that more than 2–3% of criminals' guns are obtained at these venues (Wright and Rayburn, 2012).

One active line of research whose origins can be traced directly to ACD is patterns of acquisition of firearms used in well-publicized school shootings – Sandy Hook, Newtown, Northern Illinois University, Virginia Tech, and many others. After each of these incidents, parents, teachers, and the media

always exclaim with evident exasperation, "Where did they get their guns?" The answer is that they are obtained largely through the same methods and outlets as adult offenders, i.e., via informal purchases, swaps, and trades in secondary gun market, or often enough, directly from family members. For a review of legislative responses to school shootings, see Schildkraut and Hernandez (2014).

Crime, Crime Rates, and Guns

Rates of crime in general and violent crime in particular trended upward from the 1960s to about 1994, when a downward slide occurred that has generally continued since. No one has produced the conclusive account of why violent crime rates dropped, but the decline was steep and nearly universal across the United States (Rosenfeld, 2005). Some suggest that the generally good economy of the mid- to late 1990s contributed (Hannon and DeFina, 2010), although the relationship between crime and the economy is not straightforward. Others have suggested an aging population (White, 2014) and enhanced law enforcement practices (Rosenfeld et al., 2014), yet the most salient factor seems to be a reduced demand for crack cocaine (Blumstein, 2006).

The reasons for the decline in crack usage are also not well understood. It seems that as the original crack generation grew older, stopped using, or died off, their generational 'replacements' preferred marijuana and alcohol. "Following a lag of a year or two, rates of gun violence also began to fall off" (Rosenfeld, 2004: 87). When considering 5- and 10-year trends in violent crime, that decline has continued. The 2012 violent crime total was roughly 13% below the 2008 level. Further, the 2008 level was approximately 12% that of 2003. Over recent years, it seems that the availability and use of hard-core drugs has been more consequential for crime rates than anything having to do with the availability of guns, which probably did not slacken significantly even as crime rates were plummeting.

That said, guns are still involved in an enormous number of crimes and acts of violence in this country. Last year, the BJS compiled a report on firearm violence for the years 1993–2011 (BJS, 2013). In that span, the nation suffered approximately 242 000 firearm-related fatalities and a much larger rate of nonfatal firearm victimizations. In 2011, 478 400 fatal and nonfatal violent crimes were committed with a firearm. Homicides made up approximately 2% of all firearm-related crimes, down by 39% from a high of 18 253 in 1993. Deaths by suicide with a firearm continue to outnumber homicidal deaths, with fatal firearms accidents a distant third. Of the nonfatal injuries, 31% occurred during the course of an aggravated assault and 26% occurred during the course of a robbery.

Firearm usage has been found to be exceptionally high in crime-precipitated homicides, defined as cases where the victim was killed while engaging in illegal behavior such as predatory crimes, vice crimes, or drug dealing (Copes et al., 2002). In an analysis of homicides in Chicago, Copes and colleagues found that about 64% of all crime-precipitated homicides involved a firearm. Of these, 77% of the homicides were committed in connection with predatory crime involving firearms, compared to 49% of the homicides connected to vice crimes and 89% of murders connected to drug transactions.

ACD described predatory gun criminals as relatively young nonwhite men from troubled backgrounds, usually living in violent neighborhoods. This description has been confirmed in subsequent studies. Stell (2004) found most perpetrators of homicide and other gun-related crimes to be male and younger than 30 years. Furthermore, 70–80% of firearm offenders have criminal records with an average of four felony arrests prior to the commission of a homicide.

Regarding homicide victimization, researchers have found that criminal offending increases the chances of becoming a homicide victim (Dobrin and Bursk, 2003; Dobrin et al., 2005). Faria (2005) analyzed FBI data and found that approximately 75% of violent crimes in any locality are committed by a very small minority of criminals (6%) who are the most active repeat offenders (less than 0.2% of crimes committed with firearms are committed by citizens licensed to carry a concealed weapon). Criminal activity involving firearms is disproportionately committed by and against a small subset of the population (Cook et al., 2005).

Firearms Behaviors and Criminological Theory

The number of criminals who are also victims of crime, including homicides, drives home the important theoretical point that, as ACD puts it, "these men inhabit a violent and generally hostile world…these men came to possess and carry [guns] as much to aid in surviving life on the streets as to use in committing crime" (p. 139). ACD was itself largely descriptive, but since initial publication, researchers in the field have made some theoretical developments on the subject of criminal activity and firearms.

Routine activities theory was originally developed by Cohen and Felson (1979) and argues that the opportunity to commit crime happens with the combination of a motivated offender, a suitable target, and the absence of capable guardians. Lifestyles and routine activities help control the risk of victimization. In other words, how people spend their time, when they work or leave home, how they dress, what defensive measures they take, who they spend time with, the presence or absence of guardians, etc., all impact upon their suitability as a target.

ACD drew attention to guns and gun carrying as part and parcel of the routine activities of the criminal class. Several factors affect the decision for the 'bad guys' to carry firearms routinely, including a fear or history of victimization, involvement with delinquent peer groups, exposure to violence, and a deviant or criminal lifestyle. The key 'decision' of criminals was not to acquire one or even to use a gun in a particular offense, but rather the decision to carry a gun on a routine basis. This was largely in response to a perceived dangerous and hostile environment, where a gun becomes useful in a threatening world. Once a firearm is being carried routinely, it is then available for use in crime.

Recently, researchers have been examining routine activities theory by showing how gang membership and carrying a gun can be categorized as both risk and protective factors in high-poverty areas (Spano et al., 2008). More specifically, researchers found that carrying a gun was a significant risk

factor for violent victimization. However, these effects were interceded by some lifestyles such as family relationships and employment status.

These findings have been cited as one justification for law enforcement emphasis on the detection and intervention of illegal gun carrying in crime 'hot spots,' for example, the Kansas City Gun Experiment in the early 1990s, Project Safe Neighborhoods implemented in Chicago and a number of other US cities, Project Exile in Richmond, and a number of others. A recent case study of one such program, Youth ALIVE!, found reductions in gun violence in California (Calhoun, 2013). This not-for-profit organization trained youth in California by training them to become peer educators to reduce the supply and demand for guns. These gun buyback programs, now fairly common in the United States (Goering, 2010), may take years to affect crime rates and are a topic in need of more research (Phillips et al., 2013).

Studies such as these elucidate how routine activities theory suggests a degree of rationality in criminal behavior (McCarthy, 2002). From the offender's perspective, it indicates cost–benefit calculations are being made, and that public policy solutions can thus contribute to a reduction of gun homicides. When individuals see people around them carrying guns, the act becomes a very rational act. As one respondent in ACD put it, "You can't never afford to be the only guy on the street who ain't got him a piece."

In asking ACD respondents why they carried a gun, the single most common answer among was, "if you carry a gun, your victim doesn't put up a fight and that way you don't have to hurt them" (mentioned as 'very important' by 57% of the sample). The 'bad guys' carry guns as a means of circumventing, not perpetrating, violence. Other life situations that might rationalize the routine carrying of guns would be harassment by others with guns, engaging armed victims, or having an encounter with police.

Firearms Laws and the Reduction of Gun Violence

A commonplace argument in debates about gun control is that compared to other countries, the United States has fairly relaxed firearms laws, lots and lots of guns, and more gun violence than most other countries. All of this is true. What is less obvious is the conclusion that lenient laws and ease of obtaining a firearm are the reasons why we suffer so much gun violence. In other words, would increasing laws and restrictions on firearm ownership reduce gun violence? One set of researchers (Hahn et al., 2005) attempted to answer this question by examining dozens of attempts to reduce gun violence. In their study, they considered the following firearm legislation and violence prevention attempts: firearm registration, bans on specific guns, or ammunition; 'shall issue' statutes making it easier to carry concealed weapons; restrictions on acquiring guns; acquisition waiting periods; gun licensing, laws that require childproof storage of guns; and zero-tolerance approaches to firearms in schools. Across all available studies and multiple indicators of violence, it was concluded that, "the evidence is insufficient to determine whether the degree or intensity of firearms regulation is associated with increased (or decreased) violence" (2005: 59).

In the sequel to ACD focused on juvenile offenders (Sheley and Wright, 1995), it was pointed out that since most of the methods through which criminals acquire guns are already against the law, one wonders whether new, more strict, or aggressive enforcement of existing laws will make much of a difference. The failure of existing studies to detect the presumed violence-reductive effects of more and stricter gun laws also implies that even if such effects exist, they cannot be very strong (Legault and Hendrickson, 2009). As intimated time and again throughout ACD, those who seek to reduce the level of violence in the United States by putting further and more burdensome restrictions on the rights of the general public to own firearms are probably barking up the wrong tree.

Perhaps the most well-known firearms law to have been passed since the 1980s was the Brady Act, which mandated a federal 5-day waiting period for gun acquisition and a mandatory criminal background check. The law has since been replaced with the FBI's National Instant Criminal Background Check System, itself controversial (Price and Norris, 2010). Numerous evaluations of Brady and similar legislative initiatives showed they have little to no effect in reducing firearms violence (Moorhouse and Wanner, 2006; McGarrell, 2005; Stell, 2004; Levitt, 2004; Lott and Whitley, 2001; Brezina and Wright, 2000; Ludwig and Cook, 2000). The large majority of illegal firearms transactions do not involve conventional over-the-counter retail transactions; therefore, restrictions imposed at the point of retail sale do not have much of an effect.

More generally, efforts to control violent crime by controlling the supply of firearms have been generally unsuccessful, at least partly because the vast number of guns already in circulation (several hundreds of millions) implies that actual reductions in the available supply are almost impossible to achieve (Brezina and Wright, 2000). Guns already in circulation represent a virtually inexhaustible source of supply to the informal market in firearms. And, of course, there are always corrupt 'legitimate' firearm dealers engaged in trafficking to supplement the supply of pre-owned guns.

Studies in the last 5–10 years have shown mixed results for the effects of different gun laws. A study using state data from 2007 to 2010 found that states with more gun laws had fewer firearm homicides and firearm suicides (Fleeger et al., 2013). By using five categories of firearm legislation across states, a 'legislative strength score' was created for each state. The average firearm fatality rates among states varied from a low of 2.9 fatalities (Hawaii) to a high of 17.9 (Louisiana). Firearm legislation scores ranged from a low of 0 (Utah) to a high of 24 (Massachusetts). A major limitation of the study is that the researchers could not determine causation, calling for further research on the topic.

Another study examining all 50 states (2004) gathered data on concealed carry and 'shall issue' laws (Hepburn et al., 2004). Researchers found no significant association between changes in concealed carry laws and homicide rates. Consistent with previous studies, a citizen legitimately carrying a concealed weapon does not seem to have any impact on increases or decreases in violent crime rates. This study, however, only examined data from 1979 to 1998. An array of firearm legislation since this time could show different results.

Law Enforcement Strategies and the Reduction of Gun Violence

Because of the above results, more recent efforts to control violence have looked to law enforcement rather than new legislation (Ludwig, 2005) as the potential solution. Within recent years, numerous cities have initiated 'gun emphasis' programs, directing law enforcement to target gun possession by persons with previous felony convictions. These approaches move to more aggressive enforcement of existing laws instead of enacting new laws. In general, there is little to no evidence that the number of guns legitimately owned by private citizens has a discernible effect on crime (Stolzenberg and D'Alessio, 2000). There is some indication, however, that reducing the use of firearms in crime would reduce the rate of firearm-related injuries and fatalities (Varano et al., 2004; Weaver et al., 2004).

Differing law enforcement approaches to getting guns off the streets share common thematic elements. For example, each program focuses on identifying 'hot spots' of criminal gun activity and intervening. Most of these programs also have community outreach and partnership components, and some degree of interagency cooperation efforts spanning local, state, and federal levels. A common element is the 'pulling levers' strategy, comprised essentially of 'throwing the book' at perpetrators of violence through increased focus and cooperation from law enforcement officials, prosecutors, and the courts. The general theory of 'pulling levers' is that law enforcement can deter violent behavior by reaching out to gang members and setting standards for their behavior (Corsaro et al., 2013). Law enforcement agencies then 'pull every lever' for punishment when those criterions are violated.

Although theoretically promising, the evidence is mixed on whether these programs curb gun violence. Braga and Pierce (2005) found significant reductions in firearm violence for Boston's Operation Ceasefire, but a reanalysis by Rosenfeld et al. (2005) did not confirm these. Fagin et al. (1998) found that Compstat had a lowered violent crime, but again Rosenfeld et al. (2005) disputed the result. Ironically, Rosenfeld et al. (2005) found support for the violence-reductive effects of Project Exile in Richmond, but the analysis by Raphael and Ludwig (2003) did not. The efficacy of Operation Ceasefire in Los Angeles and Atlanta's Project PACT is also questionable (Tita et al., 2005; Kellermann et al., 2006). Researchers indicated that The Indianapolis 'Directed Patrol Project' was a fairly cost-effective deterrent to firearm crime (McGarrell et al., 2002). The St. Louis Consent-to-Search program started strong, but the effect dwindled after policy changes altered the nature of the program (Decker and Rosenfeld, 2004). A mixed-methods evaluation of a pulling-levers approach in Rockford, Illinois was associated with a significant reduction in crime and drug use (Corsaro et al., 2013).

The National Institute of Justice published annual reviews on these gun enforcement strategies from 2001 to 2006, and the best that can be said is that some programs seem to have been at least marginally effective in some years under some conditions, whereas others were not.

It is hard to come to an omnibus conclusion in the face of these inconsistent results. It is difficult to control exogenous factors – such as declining crime and violent crime rates in most cities from the mid-1990s forward, employment trends, demographic changes, policing strategies, and political environments (Rosenfeld et al., 2005; Raphael and Ludwig, 2003) – in these kinds of evaluation studies.

More recently, a pulling-levers strategy adopted as part of the DOJ-sponsored Project Safe Neighborhoods was evaluated in Lowell, Massachusetts. This strategy focused on a small number of gang members who were assessed as playing a large role in citywide gun violence. This initiative included the involvement of the local police; Bureau of Alcohol, Tobacco, and Firearms (ATF); FBI; county prosecutors; probation and parole officers; and juvenile corrections caseworkers. The program combined public outreach and intervention programs with increased law enforcement, prosecutorial, and correctional attention. As a result, the intervention plan was found to have significantly decreased the amount of gun-related violence in Lowell (Braga et al., 2008).

Based on various evaluations, several things can be said regarding the efficacy of gun enforcement programs. First, problem-oriented policing (such as focusing resources heavily on a particular problem such as gun crime by youth) seems to show some potential. Also, programs with specialized directed patrol techniques ('hot spots') appear to be more effective than those with more general patrol policies. Interagency cooperation is clearly integral to gun enforcement programs. Further, 'pulling levers' only works when these agencies are all on board with the strategy. The lesson is apparently that reactive policing (where officers simply respond to calls for service) will not suffice. It is also apparent that programs work best when support is gathered from the public, and when realistic and meaningful alternatives for those involved in violent activity are provided. Unfortunately, when violent crime spikes, most people want immediate action, and things like community partnerships, community involvement, or 'community policing' take a backseat.

Abstract

Gynecological and obstetric health is closely linked to female psychological well-being and calls for a holistic bio-psychosocial and life span approach. The first section of the current contribution offers a short overview of selected gynecological disorders related to the menstrual cycle including menstrual cycle disorders, premenstrual syndrome/premenstrual dysphoric disorder, endometriosis, polycystic ovary syndrome, and infertility. Sexual dysfunctions and urinary incontinence are presented in the section on gynecological disorders not related to the menstrual cycle. Finally, psychosocial aspects of obstetric health and menopause are discussed.

Introduction

Gynecology is a medical discipline dedicated to female health care concerns including the development, diagnosis, prevention, and therapy of disorders and diseases distinct to the female reproductive system. The medical care of a women and her child before, during, and after birth is attributed to the field of obstetrics (Cunningham et al., 2010). Gynecology and obstetrics are related disciplines concerned with female reproductive health.

Across life span, women experience multiple events associated with reproductive development such as menarche, menstruation, pregnancy, maternity, and menopause. Compared to developmental events in male reproduction, these developmental events in female reproduction induce more drastic physiological alterations (e.g., menstrual bleeding, physiological changes in pregnancy, breast feeding, menopausal hormone fluctuations), more significant psychological changes and more complex psychosocial consequences for women. Though most women adapt well to these reproductive events, under certain conditions, they may develop an increased vulnerability for psychological maladjustment. Psychological problems, in turn, might exacerbate physiological symptoms associated with reproductive conditions (e.g., the influence of stress on menstrual cycle disorders). This interconnectedness between psychological and gynecological factors is reflected in findings reporting prevalence rates for mental disorders of up to 45.3% in gynecological outpatients (Leithner et al., 2009).

Female reproductive health is thus closely associated with psychological well-being and, therefore, a range of psychosocial, psychosexual, psychobiological, behavioral, and developmental psychological aspects. Consequently, gynecological and obstetric issues must be approached in a bio-psychosocial framework of health and illness that encompasses women's development and experiences across life span.

Psychosocial Aspects of Gynecological Health

Gynecological Disorders Related to the Menstrual Cycle

While menstrual cycle-related disorders can be secondary to medical conditions (e.g., cancer, hormonal dysfunctions), psychosocial (e.g., stress) and behavioral factors (e.g., excessive dieting, athletic training, obesity) may also trigger, sustain, or exacerbate these disorders. A basic biological knowledge of the female menstrual cycle is essential to understand menstrual cycle-related disorders. A short introduction is presented in the following section.

The Female Menstrual Cycle

The menstrual cycle begins with the first day of menstrual bleeding, lasts 28 days (plus or minus 3 days), and is characterized by cyclic changes within the ovary and endometrium (inside lining of the uterus).

The ovarian cycle is divided as follows:

1. the follicular phase, during which the ovarian follicle containing the immature egg cell (oocyte) develops,
2. ovulation, during which the mature egg cell (ovum) is released into the fallopian tube, and
3. the luteal phase, during which the remaining follicle cells in the ovary convert into the corpus luteum.

The corpus luteum is a transient endocrine gland that produces high levels of progesterone and moderate levels of estrogen to prepare the endometrium for potential implantation of an embryo (Cunningham et al., 2010). If no fertilization occurs, the corpus luteum withers and the concomitant decline in progesterone levels results in the shedding of the endometrium and menstrual bleeding (Henriet et al., 2012).

The endometrial cycle is divided as follows:

1. the menstrual phase, during which the top layer of the endometrium breaks down and flows out through the vagina,
2. the proliferative phase, during which the endometrium thickens, and
3. the secretory phase, during which the endometrium differentiates for preparation of implantation.

The complex processes of the female menstrual cycle are controlled by the hormones of the hypothalamic-pituitary-ovarian (HPO) axis. The hypothalamus releases gonadotropin-releasing-hormone (GnRH) in a pulsatile fashion, and induces a pulsatile secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the anterior pituitary into the blood stream. In the ovaries, FSH and LH stimulate the

production of progesterone and estrogen, which exert their influences on the endometrium and other end organs and send negative and positive feedback signals to the pituitary and hypothalamus (Hoffman et al., 2012). For example, during the follicular phase, FSH stimulates the growth of follicles (Beshay and Carr, 2013). In response, cells surrounding the follicle start producing estrogen to further advance follicular development. The increasing estrogen concentrations trigger a LH surge, which ultimately leads to ovulation (Hawkins and Matzuk, 2008). Thus, during this phase of the menstrual cycle a positive feedback loop is established.

While estrogen production by the ovaries dominates during the follicular phase, progesterone production dominates during the luteal phase (Snowdon and Ziegler, 2007).

The HPO axis activity is influenced by numerous hormones including those of the hypothalamic-pituitary-adrenal (HPA) axis, which are released in response to psychosocial stress (Snowdon and Ziegler, 2007). For instance, corticotrophin-releasing hormone (CRH) and cortisol have an inhibiting effect on GnRH and LH secretion. This is thought to explain, at least in part, how stress might negatively affect gynecological health.

Menarche

Menarche is the first menstrual period in adolescent girls and occurs at an average age of 13.5 years (Thomas et al., 2001). It marks the beginning of the reproductive phase in the life of a woman.

The degree to which young girls are prepared for menstruation varies. Often they receive information from their mothers, female peers, and the media (van den Akker, 2012). While, the hygienic aspect generally tends to be emphasized, biological, practical, and psychological information seem to be neglected (e.g., menstrual cycle as something normal and natural; as a method to monitor gynecological health). Accordingly, many young girls tend to have a negatively biased or ambivalent attitude toward menarche and menstruation (Stubbs, 2008).
